#### Abstract

We study three kinetic Langevin samplers including the Euler discretization, the BU and the UBU splitting scheme. We provide contraction results in $L^{1}$-Wasserstein distance for non-convex potentials. These results are based on a carefully tailored distance function and an appropriate coupling construction. Additionally, the error in the $L^{1}$-Wasserstein distance between the true target measure and the invariant measure of the discretization scheme is bounded. To get an $\varepsilon$-accuracy in $L^{1}$-Wasserstein distance, we show complexity guarantees of order $\mathcal{O}(\sqrt{d} / \varepsilon)$ for the Euler scheme and $\mathcal{O}\left(d^{1 / 4} / \sqrt{\varepsilon}\right)$ for the UBU scheme under appropriate regularity assumptions on the target measure. The results are applicable to interacting particle systems and provide bounds for sampling probability measures of mean-field type.

Keywords and phrases: Kinetic Langevin sampler, Langevin dynamics, Convergence to equilibrium, Coupling, discretization schemes.

## 1. Introduction

We are interested in the long-time behaviour of discretizations of the kinetic Langevin dynamics on $\mathbb{R}^{2 d}$ given by

$$
\left\{\begin{array}{l}
\mathrm{d} X_{t}=V_{t} \mathrm{~d} t  \tag{1}\\
\mathrm{~d} V_{t}=-\nabla U\left(X_{t}\right) \mathrm{d} t-\gamma V_{t} \mathrm{~d} t+\sqrt{2 \gamma} \mathrm{~d} B_{t}
\end{array}\right.
$$

where $U$ is a twice-differential potential, $\gamma>0$ denotes the friction parameter and $\left(B_{t}\right)_{t \geq 0}$ is a $d$-dimensional standard Brownian motion. Apart from its origin to model phenomena occurring in physics, this dynamics is applied to sample a given probability distribution $\mu^{x}(\mathrm{~d} x) \propto \exp (-U(x)) \mathrm{d} x$ on $\mathbb{R}^{d}$. The distribution is the marginal of the Boltzmann-Gibbs distribution $\mu(\mathrm{d} x \mathrm{~d} v) \propto \exp \left(-U(x)-|v|^{2} / 2\right) \mathrm{d} x \mathrm{~d} v$ on $\mathbb{R}^{2 d}$ forming the stationary distribution of (1). As observed in [17], these dynamics provide a faster convergence behaviour than for example the overdamped Langevin dynamics $\mathrm{d} X_{t}=-\nabla U\left(X_{t}\right) d t+\sqrt{2} \mathrm{~d} B_{t}$ with stationary distribution $\mu^{x}$, which after an appropriate time-rescaling is the high-friction limit of (1).

As in simulations, the exact dynamics are not accessible in general, in practice the dynamics need to be discretized by a numerical scheme. There are many different choices of numerical scheme that have been proposed for kinetic Langevin dynamics from the molecular dynamics community (see $[28,42,39,15,63,14,51,40]$ ) as well as the machine learning and the MCMC community (see $[60,22,31,32,8]$ ). We consider three discretization schemes of the kinetic Langevin dynamics. First, we analyse the explicit Euler-Maruyama scheme which is a simple but straightforward scheme to implement.

Secondly, we consider the two more elaborate splitting schemes, BU and UBU, which were introduced in $[62,66]$. These two splitting schemes rely on the fact that the dynamics are split into two parts, i.e., $U$ and $B$, and each of them is integrated exactly (in the weak sense). As the names of the splitting schemes suggest, for discretization parameter $h>0$, the schemes
are constructed by performing a $B$ step before a $U$ step for the BU scheme. Alternatively, a half $U$ step (of size $h / 2$ ), then a full $B$ step and finally another half $U$ step of size $h / 2$ is realised for the UBU scheme $[62,66,58,18]$.

In the analysis of the long-time performance of the three schemes, we aim to understand the influences of a non-convex potential including multi-well potentials. Here, we will assume that $U$ is $\kappa$-strongly convex outside of a Euclidean ball with radius $R>0$ and has an $L$ Lipschitz continuous gradient. This setting is very important in applications in molecular dynamics and Bayesian inference (see for example [41] and [37]), where the potentials can be highly multimodal.

Before presenting our own contribution, let us first highlight the existing results for the kinetic Langevin sampler. Already the study of the long-time behaviour of the continuous dynamics has attracted enormous interest through many techniques including Lyapunov techniques (see [65, 47]), hypocoercivity techniques (see [64, 26, 27, 2, 3, 4, 1, 17, 13]), and coupling techniques (see [30, 59]).

It is also important to quantify the long-time behaviour of the discretizations of kinetic Langevin dynamics, as these are implemented in practice in many applications. In combination with bias estimates these result in non-asymptotic guarantees for the implemented algorithms. The long-time behaviour of kinetic Langevin dynamics discretizations have also been studied by various techniques including Lyapunov arguments (see [28, 41]), coupling methods (see $[22,24,54,58,43,34,44]$ in the convex setting and [21, 19] in the non-convex setting) and recently hypocoercivity approaches have been extended to certain discretizations (see [55] and [16]).

The focus of this paper is using coupling methods to study the long-time behaviour of the kinetic Langevin sampler. This is a recently popular approach to study sampling algorithms and their non-asymptotic guarantees. It includes overdamped Langevin dynamics-based sampling methods and Hamiltonian dynamics-based sampling methods, which can be united by variants of the OBABO integrator (see [34] and [19] for generalized Hamiltonian Monte Carlo). Non-asymptotic guarantees for Hamiltonian Monte Carlo methods have been studied in $[46,7,11,12,9,34,16,55]$ and also Langevin Monte Carlo methods in [23, 29].

Our main contribution is twofold. First, we establish contraction in Wasserstein distance for each scheme. To our knowledge, this is the first contraction result in a non-globally convex setting for these discretization schemes. More precisely, we adapt the idea of the coupling of [19] for OBABO to the discretization schemes considered here, construct a distance function $\rho$ which is based on the one in [59] and show that contraction in $L^{1}$-Wasserstein distance with respect to the distance $\rho$ holds for the Euler and the BU scheme. The results hold provided the step size is sufficiently small and the friction parameter $\gamma$ is sufficiently large. This is consistent with the observations in the continuous case. Since $\rho$ is equivalent to the Euclidean distance and contraction for the UBU scheme can be deduced up to an additional factor from the contraction for the BU scheme, we obtain exponential decay in the classical $L^{1}$ Wasserstein distance for all three schemes, i.e.,

$$
\mathcal{W}_{1}\left(\mu_{k}, \nu_{k}\right) \leq \mathbf{M} e^{-c k h} \mathcal{W}_{1}\left(\mu_{0}, \nu_{0}\right),
$$

where $\mu_{k}$ and $\nu_{k}$ denotes the law after $k$ discretization steps. The contraction rate $c>0$ and the constant $\mathbf{M}>0$ are independent of the step size $h$ and the dimension $d$. This result implies existence of a unique invariant measure and convergence towards it for each scheme.
Secondly, we give an error analysis and establish complexity guarantees for each scheme. More precisely we bound the asymptotic bias $\mathcal{W}_{1}\left(\mu_{h, \infty}, \mu\right)$, where $\mu_{h, \infty}$ is the invariant measure of the discretized process with step size $h$ and $\mu$ is the invariant measure of (1). Inspired by the strong convergence of numerical solutions of SDEs [52, Theorem 1.1] we are able to only lose an order of $1 / 2$ accuracy from local to global strong error estimates in terms of
stepsize $h>0$. That is an asymptotic bias of order one for the Euler-Maruyama scheme and order two under additional smoothness assumptions for the UBU scheme. For the UBU integrator, we achieve second-order asymptotic bias estimates inspired by the work of [58], but in comparison to [58]'s approach we achieve this by using the independence of the Brownian increments during each iteration and average over multiple steps, which is the approach we use for analysis of both integrators to achieve bias estimates in the constructed distance function.

Combining these results for the Euler-Maruyama scheme we have complexity guarantees of order $\mathcal{O}(\sqrt{d} / \epsilon)$ to reach an accuracy of $\epsilon>0$ in $\mathcal{W}_{1}$ for the Euler-Maruyama scheme and additionally for the UBU scheme when combining the respective UBU results. Under additional smoothness assumptions, we can achieve complexity guarantees of order $\mathcal{O}(\sqrt{d} / \sqrt{\epsilon})$ for the UBU scheme and under a stronger smoothness condition complexity guarantees of order $\mathcal{O}\left(d^{1 / 4} / \sqrt{\epsilon}\right)$, which is true for many applications of interest.

Finally, we remark that the contraction and complexity results can be carried over to interacting particle models with pairwise interactions (see Remark 3 and Remark 5). These models play an important role for instance in modelling granular media in physics [5], in molecular dynamics problems using a harmonic or Morse interaction potential (see for example [41, Chapter 1]) or two-layer Neural Networks in deep learning [36, 49, 57, 61]. As the number of particles in the model tends to infinity, the target measure becomes the stationary measure of a distribution-dependent version of the kinetic Langevin dynamics (see Equation (13)). Using particlewise adaptations of the coupling and the distance function, contraction results independent of the particle number are proven both for the continuous kinetic Langevin dynamics $[6,38,35,59]$ and for kinetic samplers $[16,12]$. The two latter papers also provide complexity guarantees of sampling this type of measure. Our paper contributes to the analysis of kinetic samplers by providing bounds in this setting for the Euler, BU and UBU discretization.

The paper is organized in the following way. In Section 2, we define rigorously the discretization schemes and state the precise framework. In Section 3 the contraction results are stated for the different discretization schemes followed by the accuracy analysis of these schemes and numerical illustrations of the contraction results. The metric and coupling construction and the proofs are postponed to Section 4 and Section 5.

## 2. Discretization schemes and preliminaries

### 2.1. Euler-Maruyama discretization

The simplest discretization of (1) is a simple explicit Euler discretization of the dynamics. For given discretization parameter $h>0$, the scheme is given by

$$
\left\{\begin{array}{l}
\mathbf{X}_{k+1}=\mathbf{X}_{k}+h \mathbf{V}_{k}  \tag{2}\\
\mathbf{V}_{k+1}=\mathbf{V}_{k}-h \nabla U\left(\mathbf{X}_{k}\right)-h \gamma \mathbf{V}_{k}+\sqrt{2 \gamma h} \xi_{k+1}
\end{array}\right.
$$

where $\left(\xi_{k}\right)_{k \in \mathbb{N}}$ is a sequence of independent normally distributed random variables. This discretization scheme has strong local error of the order $3 / 2$ and global strong error of order 1 (see [53, Theorem 1.1]).

### 2.2. Splitting Methods and the UBU discretization

More advanced numerical schemes of (1) can be made by the use of splitting methods, where the dynamics are split into different components (deterministic and stochastic) which can be integrated exactly in the weak sense. We refer the reader to [48] for a comprehensive
introduction to splitting methods. By careful design of the appropriate splittings one can create high order numerical methods in the strong and the weak sense [39, 15].

A class of splitting schemes which are typically used in molecular dynamics (see [41]) are based on splitting the SDE (1) in the following way

$$
\binom{d x}{d v}=\underbrace{\binom{0}{-\nabla U(x) d t}}_{\mathcal{B}}+\underbrace{\binom{v d t}{0}}_{\mathcal{A}}+\underbrace{\binom{0}{-\gamma v d t+\sqrt{2 \gamma} d W_{t}}}_{\mathcal{O}},
$$

where the $\mathcal{B}, \mathcal{A}$ and $\mathcal{O}$ parts can be integrated exactly over a time interval of size $h>0$ and composed in different orders to produce different splitting methods. These include the popular integrators BAOAB, OBABO and OABAO, where palindromic sequences produce weak order two numerical methods [39]. The OBABO and OABAO integrators have been studied in the context of non-asymptotic guarantees in [19, 54, 16, 34, 10]. These methods are weak order two, but are only strong order one.

Strong order methods are particularly important in the context of multilevel Monte Carlo [33] and recently in unbiased estimation [18]. An alternative splitting first introduced in [62] requires only one gradient evaluation per step, yet surprisingly is globally strong order two. It is based on splitting the $\operatorname{SDE}$ (1) into the following components

$$
\binom{d x}{d v}=\underbrace{\binom{0}{-\nabla U(x) d t}}_{\mathcal{B}}+\underbrace{\binom{v d t}{-\gamma v d t+\sqrt{2 \gamma} d W_{t}}}_{\mathcal{U}},
$$

which can be integrated in the weak sense exactly over an interval of size $h>0$. As in the earlier methods, we can compose the maps corresponding to the exact integration of the $\mathcal{B}$ and $\mathcal{U}$ parts to design numerical integrators of kinetic Langevin dynamics. [66] consider the BUB and the UBU methods. The UBU integrator with step size $h>0$ is defined by a half step in $\mathcal{U}$ (of size $h / 2$ ) followed by a full $\mathcal{B}$ step (of size $h$ ), followed by a half $\mathcal{U}$ step (of size $h / 2)$. Let us define $\eta=\exp (-\gamma h)$ then the operators corresponding to these maps are given by

$$
\begin{equation*}
\mathcal{B}(x, v, h)=(x, v-h \nabla U(x)), \tag{3}
\end{equation*}
$$

and

$$
\begin{align*}
& \mathcal{U}\left(x, v, h, \xi^{(1)}, \xi^{(2)}\right)=\left(x+\frac{1-\eta}{\gamma} v+\sqrt{\frac{2}{\gamma}}\left(\mathcal{Z}^{(1)}\left(h, \xi^{(1)}\right)-\mathcal{Z}^{(2)}\left(h, \xi^{(1)}, \xi^{(2)}\right)\right)\right.  \tag{4}\\
&\left.v \eta+\sqrt{2 \gamma} \mathcal{Z}^{(2)}\left(h, \xi^{(1)}, \xi^{(2)}\right)\right)
\end{align*}
$$

where

$$
\begin{align*}
\mathcal{Z}^{(1)}\left(h, \xi^{(1)}\right) & =\sqrt{h} \xi^{(1)}, \\
\mathcal{Z}^{(2)}\left(h, \xi^{(1)}, \xi^{(2)}\right) & =\sqrt{\frac{1-\eta^{2}}{2 \gamma}}\left(\sqrt{\frac{1-\eta}{1+\eta} \cdot \frac{2}{\gamma h}} \xi^{(1)}+\sqrt{1-\frac{1-\eta}{1+\eta} \cdot \frac{2}{\gamma h}} \xi^{(2)}\right), \tag{5}
\end{align*}
$$

and $\xi^{(1)}, \xi^{(2)} \sim \mathcal{N}\left(0, I_{d}\right)$ are independent standard normal random variables. UBU integration scheme with stepsize $h>0$ is defined by

$$
\begin{align*}
\left(x_{k+1}, v_{k+1}\right) & =\mathcal{U B U}\left(x_{k}, v_{k}, h, \xi_{k+1}^{(1)}, \xi_{k+1}^{(2)}, \xi_{k+1}^{(3)}, \xi_{k+1}^{(4)}\right) \\
& =\mathcal{U}\left(\mathcal{B}\left(\mathcal{U}\left(x_{k}, v_{k}, h / 2, \xi_{k+1}^{(1)}, \xi_{k+1}^{(2)}\right), h\right), h / 2, \xi_{k+1}^{(3)}, \xi_{k+1}^{(4)}\right), \tag{6}
\end{align*}
$$

where $\xi_{k+1}^{(i)} \sim \mathcal{N}\left(0, I_{d}\right)$ for all $i=1, \ldots, 4$ and $k \in \mathbb{N}$. The UBU integration scheme's nonasymptotic guarantees were first studied in [58], where discretization analysis provided global strong order two estimates under an additional smoothness assumption. This integrator was also studied in [18] with stochastic gradient methods which allow strong order $3 / 2$ with non-asymptotic guarantees.
Remark 1. [60] and [8] introduce discretizations for kinetic Langevin dynamics which randomize the point at which the gradient is evaluated resulting in improved dimension-dependence without additional smoothness. The methods we develop in this work could equally be used to prove convergence of these methods by coupling the times at which the force evaluations take place. This could then be combined with discretization analysis to achieve non-asymptotic guarantees, but this was not the focus of the current work.

### 2.3. Assumptions

We impose the following assumption on the potential $U$.
Assumption 1. The potential $U$ is $\kappa$-strongly convex outside a Euclidean ball with radius $R \geq 0$, i.e., there exists $\kappa>0$ and $R \geq 0$ such that

$$
(\nabla U(x)-\nabla U(y))(x-y) \geq \kappa|x-y|^{2} \quad \text { for } x, y \in \mathbb{R}^{d} \text { such that }|x-y|>R .
$$

Moreover, $\nabla U$ is $L$-Lipschitz continuous.
From this condition on $U$ we deduce, that $U$ can be split in an quadratic term and in a term which is convex outside an Euclidean ball, i.e., $U(x)=\frac{1}{2} x^{T} K x+G(x)$, where the function $G$ satisfies

$$
(\nabla G(x)-\nabla G(y))(x-y) \geq 0 \quad \text { for } x, y \in \mathbb{R}^{d} \text { such that }|x-y|>R .
$$

and the matrix $K$ is positive-definite and symmetric with smallest eigenvalue $\kappa>0$. We denote by $L_{G}$ the Lipschitz constant of the gradient of the function $G$ and by $L_{K}$ the Lipschitz constant of the function $x \mapsto K x$. We note that this splitting is not unique and a possible choice for $K$ is always given by $K=\kappa I_{d}$, which is not necessarily the optimal one.

### 2.4. Sketch of the distance function and the coupling

Next, we give a rough sketch of the construction of the coupling and the accompanying metric and demonstrate how they lead to contraction in Wasserstein distance for the discretization schemes.
For the Euler discretization, consider two sets of normally distributed random variables $\left(\xi_{k}\right)_{k \in \mathbb{N}}$ and $\left(\xi_{k}^{\prime}\right)_{k \in \mathbb{N}}$. Given initial values $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{2 d}$, let $\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)_{k \in \mathbb{N}}$ be the coupling of two solutions to (2) with $\left(\xi_{k}\right)_{k \in \mathbb{N}}$ and $\left(\xi_{k}^{\prime}\right)_{k \in \mathbb{N}}$, respectively. Denote by $\left(Z_{k}, W_{k}\right)_{k \in \mathbb{N}}=\left(\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}\right)_{k \in \mathbb{N}}$ the difference process of the two copies. If the difference process is far apart from the origin, we consider a twisted 2 -norm $r_{l}(k)$ as in the continuous setting [59]. Using a synchronous coupling, i.e., $\xi_{k}=\xi_{k}^{\prime}$, the noise cancels in the difference process and we show local contraction for this norm thanks to Assumption 1 and the discretized part of the Ornstein-Uhlenbeck part of the Langevin dynamics. If the difference process is close to the origin, we consider a distance function of the form $r_{s}(k)=\alpha\left|Z_{k}\right|+\left|q_{k}\right|$ with $q_{k}=Z_{k}+\gamma^{-1} W_{k}$. It holds for the process $\left(Z_{k}, q_{k}\right)_{k}$

$$
\left\{\begin{array}{l}
Z_{k+1}=Z_{k}+h \gamma\left(q_{k}-Z_{k}\right) \\
q_{k+1}=q_{k}-h \gamma^{-1}\left(\nabla U\left(\mathbf{X}_{k}\right)-\nabla U\left(\mathbf{X}_{k}^{\prime}\right)\right)+\sqrt{2 \gamma^{-1} h}\left(\xi_{k+1}-\xi_{k+1}^{\prime}\right) .
\end{array}\right.
$$

Fig 1: Level sets of the distances: The green rectangle shows a level set of the distance $r_{s}$, while the blue ellipse shows a level set of the distance $r_{l}$. The red deformed rectangle illustrates the transition between the two distances. Outside the red rectangle and on the gray dashed line the synchronous coupling is considered while inside the red rectangle the coupling from [7] is applied.

Then, for $q_{k}=0$ and $\xi_{k}=\xi_{k}^{\prime}$, the first term in the distance function decreases due to the first equation and the contribution of the second term in the distance function can be controlled by the first one by choosing the parameter $\alpha$ sufficiently large. Note that thanks to the synchronous coupling we do not have disturbance by the noise. Apart from $q_{k}=0$ we want to use the noise to get closer to the line $q_{k}=0$. In contrast to the continuous case we do not use a completely reflecting coupling, since in the case the process is already close to the line $q_{k}=0$, the reflected noise can not be controlled. We rather consider the coupling introduced for HMC in [7], which is applied to analyse OBABO in [19]. Here we have a transition from the synchronous coupling on the line $q_{k}=0$ to a reflection coupling if the difference process is far away from the line. Note that if $h$ tends to zero, we recover the coupling from [30]. If the difference process is close to the origin, i.e., $\alpha\left|Z_{k}\right|+\left|q_{k}\right|<R_{1}$ for some constant $R_{1}$, local contraction on average is shown for the distance $f\left(r_{s}(k)\right)$, where $f$ is an appropriate concave function. As in [59], the two distances $f\left(r_{s}(k)\right)$ and $r_{l}$ are continuously glued to a joint distance function such that the two local contraction results imply a global one. The transition between the two distances is illustrated in Figure 1.
For the BU scheme, two sets of normally distributed random variables $\left(\xi_{k}^{(1)}, \xi_{k}^{(2)}\right)_{k \in \mathbb{N}}$ and $\left(\xi_{k}^{(1)^{\prime}}, \xi_{k}^{(2)^{\prime}}\right)_{k \in \mathbb{N}}$ are considered for the coupling. In this case, $\xi_{k}^{(1)}$ and $\xi_{k}^{(1)^{\prime}}$ are coupled as $\xi_{k}$ and $\xi_{k}^{\prime}$ in the Euler scheme, whereas the random variables $\xi_{k}^{(2)}$ and $\xi_{k}^{(2) \prime}$ are coupled synchronously. For the same distance function as in the Euler scheme, global contraction is shown by proving two local contraction result.

The UBU scheme is analysed using the coupling and the result for the BU scheme. Namely for given $k \in \mathbb{N}, k \mathcal{U}_{1 / 2} \mathcal{B} \mathcal{U}_{1 / 2}$ steps can be split to

$$
\left(\mathcal{U}_{1 / 2} \mathcal{B \mathcal { U } _ { 1 / 2 } ) ^ { k } = \mathcal { U } _ { 1 / 2 } ( \mathcal { B U } ) ^ { k - 1 } ( \mathcal { B } \mathcal { U } _ { 1 / 2 } ) , . , ~}\right.
$$

here $\mathcal{U}_{1 / 2}$ denotes a $\mathcal{U}$ step with size $h / 2$. Then for $(k-1) \mathcal{B} \mathcal{U}$ steps the known contraction result is used. The missing steps $\mathcal{U}_{1 / 2}$ and $\mathcal{B} \mathcal{U}_{1 / 2}$ are controlled using a synchronous coupling for the random variables and noting that the distance can be controlled for these steps by the fact that $\nabla U$ is $L$-Lipschitz continuous.

## 3. Main results

### 3.1. Contraction for the Euler-Maruyama scheme

We state the contraction result for the Euler-Maruyama scheme given by (2).
Theorem 1 (Contraction for the Euler-Maruyama scheme). Let $U$ satisfy Assumption 1. Let $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{2 d}$. Let $\gamma>0$ and $h>0$ satisfy

$$
\begin{align*}
& \gamma \geq 4 L_{G} / \sqrt{\kappa} \quad \text { and }  \tag{7}\\
& L \gamma^{-1} h \leq \min \left(\frac{1}{8 L R_{1}^{2}}, \frac{1}{256 \cdot 75\left(2 L \gamma^{-2}+1\right)}, \frac{L \gamma^{-2}}{8}, \frac{L}{32 L_{K}}\right) \tag{8}
\end{align*}
$$

Then there exists a distance $\rho: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ such that for all $k \in \mathbb{N}$

$$
\begin{equation*}
\mathbb{E}\left[\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right] \leq(1-c h)^{k} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \tag{9}
\end{equation*}
$$

where the contraction rate $c$ is given by

$$
\begin{equation*}
c=\min \left(f^{\prime}\left(R_{1}\right) \frac{\epsilon \kappa \gamma^{-1}}{8} \mathcal{E}, f^{\prime}\left(R_{1}\right) \frac{\epsilon \gamma}{16} \mathcal{E}, f^{\prime}\left(R_{1}\right) \frac{\gamma}{8}, f^{\prime}\left(R_{1}\right) \frac{\gamma \alpha}{2}, \frac{\hat{c}}{128(4 \alpha+1)}\right) \tag{10}
\end{equation*}
$$

The definition of the distance function $\rho: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ and the constants $\epsilon, \alpha, \hat{c}, \mathcal{E}$ and $R_{1}$ are independent of $d$ and $h$ and are given in Section 4.1.

Proof. The proof is given in Section 5.1.
Consider two probability measures $\mu_{0}, \nu_{0}$ on $\mathbb{R}^{2 d}$. Let $\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right)$ and $\left(\mathbf{X}_{0}^{\prime}, \mathbf{V}_{0}^{\prime}\right)$ be distributed with respect to $\mu_{0}$ and $\nu_{0}$, respectively. Then, we denote by $\mu_{k}=\operatorname{Law}\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)$ and $\nu_{k}=\operatorname{Law}\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)$ the laws of the discretised kinetic Langevin sampler after $k \in \mathbb{N}$ steps, respectively.

Corollary 2 (Contraction in $L^{1}$-Wasserstein distance). Suppose Assumption 1, (7) and (8) hold. Then, for $k \in \mathbb{N}$

$$
\begin{align*}
& \mathcal{W}_{\rho}\left(\mu_{k}, \nu_{k}\right) \leq \exp (-c k h) \mathcal{W}_{\rho}\left(\mu_{0}, \nu_{0}\right)  \tag{11}\\
& \mathcal{W}_{1}\left(\mu_{k}, \nu_{k}\right) \leq \mathbf{M} \exp (-c k h) \mathcal{W}_{1}\left(\mu_{0}, \nu_{0}\right) \tag{12}
\end{align*}
$$

where $c$ is given by (10), and $\mathbf{M}$ is given in (30). Both constants are independent of $d$ and $h$. Moreover, existence of a unique invariant measure $\mu_{h, \infty}$ and convergence towards its holds, i.e., for $k \in \mathbb{N}$

$$
\begin{aligned}
& \mathcal{W}_{\rho}\left(\mu_{k}, \mu_{h, \infty}\right) \leq \exp (-c k h) \mathcal{W}_{\rho}\left(\mu_{0}, \mu_{h, \infty}\right) \\
& \mathcal{W}_{1}\left(\mu_{k}, \mu_{h, \infty}\right) \leq \mathbf{M} \exp (-c k h) \mathcal{W}_{1}\left(\mu_{0}, \mu_{h, \infty}\right)
\end{aligned}
$$

Proof. The results follow immediately from Theorem 1 and the fact that $\rho$ is equivalent to the Euclidean distance. Existence of a unique invariant measure holds by Banach fixed point theorem.

Remark 2. We note that for the strongly convex case the contraction rate reduces to $c=$ $\min \left(\kappa /\left(8 \gamma^{2}\right), 1 / 16\right) \gamma$ and is maximized for $\kappa=\gamma^{2} / 2$. If $L_{G} \leq \sqrt{8} \kappa$, the condition $\gamma \geq 4 L_{G} / \sqrt{\kappa}$ is satisfied. Hence, for small perturbations of the Gaussian case, we obtain that the contraction rate given by $c=\gamma / 16=\sqrt{2 \kappa} / 16$ is of optimal order in $\kappa$.

Remark 3 (Particle model). As in the continuous case ([59]), the convergence result can be carried over to show convergence for a particle system with $N \in \mathbb{N}$ particles, where the potential $U: \mathbb{R}^{d N} \rightarrow \mathbb{R}$ is of the form

$$
U(\mathbf{x})=\sum_{i=1}^{N}\left(V\left(x^{i}\right)+\frac{1}{N} \sum_{j=1, j \neq i}^{N} W\left(x^{i}-x^{j}\right)\right)
$$

with confining potential $V: \mathbb{R}^{d} \rightarrow \mathbb{R}$ and interaction potential $W: \mathbb{R}^{d} \rightarrow \mathbb{R}$. In this case, contraction can be shown in $L^{1}$-Wasserstein distance with respect to a particlewise adaptation of the distance $\rho$ and the Euclidean distance, i.e.

$$
\rho_{N}\left((\mathbf{x}, \mathbf{v}),\left(\mathbf{x}^{\prime}, \mathbf{v}^{\prime}\right)\right)=\frac{1}{N} \sum_{i=1}^{N} \rho\left(\left(x^{i}, v^{i}\right),\left(x^{i^{\prime}}, v^{i^{\prime}}\right)\right), \quad \text { and } \quad \ell_{1}^{N}=\frac{1}{N} \sum_{i=1}^{N}\left|\left(x^{i}, v^{i}\right)-\left(x^{i^{\prime}}, v^{i^{\prime}}\right)\right|
$$

provided that the interaction potential has Lipschitz continuous gradient and the Lipschitz constant is sufficiently small compared to the strong convexity constant $\kappa$. Following [59], the condition on the Lipschitz coefficient is needed in this approach to handle the interaction as an additional perturbation. In this case, contraction for the particle system is of the form

$$
\mathcal{W}_{\rho_{N}}\left(\mu_{k}^{N}, \nu_{k}^{N}\right) \leq \exp (-c k h) \mathcal{W}_{\rho_{N}}\left(\mu_{0}^{N}, \nu_{0}^{N}\right)
$$

where $\mu_{k}^{N}$ and $\nu_{k}^{N}$ denote the law of the discretized Langevin dynamics for the $N$-particle system and $c$ is the contraction rate which is independent of $N$ and which will be of the same form as the contraction rate in (10) up to some constant prefactor.

### 3.2. Complexity guarantees for the Euler-Maruyama scheme

Next, we bound the distance between the target measure $\mu_{\infty}(\mathrm{d} x) \propto \exp \left(-U(x)-|v|^{2} / 2\right) \mathrm{d} x$ and the invariant measure $\mu_{h, \infty}$ of (2).

Theorem 3 (Strong accuracy). Suppose Assumption 1, (7) and (8) hold. Then,

$$
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \leq h\left(1+\frac{\gamma\left(1+2 L \gamma^{-2}\right)}{c}\right) 20 L \gamma^{-2} \sqrt{d}
$$

where $c$ is given in (10).
Proof. The proof is given in Section 5.
Given a probability measure $\nu_{0}$ on $\mathbb{R}^{2 d}$ let $\nu_{k}$ denote the law of the Euler discretization after $k \in \mathbb{N}$ steps. Using the strong accuracy result, we bound the distance between $\nu_{k}$ and the target measure $\mu_{\infty}$.

Theorem 4. Suppose Assumption 1, (7) and (8) hold. Then for $k \in \mathbb{N}$,

$$
\begin{aligned}
& \mathcal{W}_{\rho}\left(\mu_{\infty}, \nu_{k}\right) \leq h\left(1+\frac{\gamma\left(1+2 L \gamma^{-2}\right)}{c}\right) 20 L \gamma^{-2} \sqrt{d}+e^{-c h k} \mathcal{W}_{\rho}\left(\mu_{h, \infty}, \nu_{0}\right), \\
& \mathcal{W}_{1}\left(\mu_{\infty}, \nu_{k}\right) \leq \mathbf{N} h\left(1+\frac{\gamma\left(1+2 L \gamma^{-2}\right)}{c}\right) 20 L \gamma^{-2} \sqrt{d}+\mathbf{M} e^{-c h k} \mathcal{W}_{\rho}\left(\mu_{h, \infty}, \nu_{0}\right),
\end{aligned}
$$

where $c$ is given in (10), $\mathbf{M}$ and $\mathbf{N}$ are given in (30)-(31).
Proof. The proof is given in Section 5.

Remark 4 (Complexity guarantees). To obtain an $\varepsilon$-accuracy in $\mathcal{W}_{1}$ distance, we have to choose $h \propto \varepsilon / \sqrt{d}$ and the number of steps $k$ of order $k \propto \log (\Delta(0) / \varepsilon) /(c h)$. Here $\Delta(0)=$ $\mathcal{W}_{1}\left(\mu_{h, \infty}, \nu_{0}\right)$. Since in each step there is one gradient evaluation, the number of gradient evaluation for $\varepsilon$-accuracy is of order $\sqrt{d} / \epsilon$.
Remark 5 (Particle model and propagation of chaos). Bounds on the strong accuracy can also be considered for the particle model (see Remark 3). Note that due to the fact that a normalized distance $\rho_{N}$ is considered, the bound between the target measure $\mu_{\infty}^{N}$ of the particle system and the law after $k$-steps of the discretized Langevin dynamics is independent of the particle number $N$. Further, combining this bound with the propagation of chaos result given in [59, Theorem 17], it holds under the assumptions in Theorem 4 and a smallness assumption for the Lipschitz constant of the gradient of the interaction potential in the particle system that the distance between the law after $k$-steps of the discretized Langevin dynamics with $N$ particles and the stationary measure $\mu_{*}$ of the limit process given by

$$
\begin{equation*}
\mu_{*}(\mathrm{~d} x) \propto \exp \left(-V(x)-\int_{\mathbb{R}^{d}} W(x-y) \mu_{*}(\mathrm{~d} y)\right) \mathrm{d} x \tag{13}
\end{equation*}
$$

is bounded by

$$
\mathcal{W}_{\ell_{1}^{N}}\left(\mu_{k}^{N}, \mu_{*}^{\otimes N}\right) \leq C\left(e^{-c h k} \mathcal{W}_{1}\left(\mu_{0}, \mu_{*}\right)+\sqrt{d} h+N^{-1 / 2}\right)
$$

Here, the constant $C>0$ is independent of $N, d$ and $h$.

### 3.3. Contraction for the $B U$ and $U B U$ scheme

Consider the Markov chain $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)_{k \in \mathbb{N}}$ generated by the BU-discretization scheme.
Theorem 5 (Contraction for the BU discretization scheme). Let $U$ satisfy Assumption 1. Let $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{d}$. Let $\gamma>0$ and $h>0$ satisfy

$$
\begin{align*}
& \gamma \geq \sqrt{13 L_{G}^{2} / \kappa} \quad \text { and }  \tag{14}\\
& L \gamma^{-1} h \leq \min \left(\frac{1}{8 L R_{1}^{2}}, \frac{1}{256 \cdot 75\left(2 L \gamma^{-2}+1\right)}, \frac{L \gamma^{-2}}{15}, \frac{L}{55 L_{K}}\right) \tag{15}
\end{align*}
$$

Then there exists a distance $\rho: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ such that for any $k \in \mathbb{N}$ it holds

$$
\begin{equation*}
\mathbb{E}\left[\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right] \leq(1-c h)^{k} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \tag{16}
\end{equation*}
$$

where the contraction rate $c$ is given by

$$
\begin{equation*}
c=\min \left(f^{\prime}\left(R_{1}\right) \frac{7 \epsilon \kappa \gamma^{-1}}{96} \mathcal{E}, f^{\prime}\left(R_{1}\right) \frac{7 \epsilon \gamma}{256} \mathcal{E}, f^{\prime}\left(R_{1}\right) e^{-\gamma h} \frac{\gamma}{16}, f^{\prime}\left(R_{1}\right) e^{-\gamma h} \frac{\gamma \alpha}{4}, \frac{1}{128(4 \alpha+1)} \hat{c}\right) \tag{17}
\end{equation*}
$$

The construction of the distance function $\rho$ and the constants $R_{1}, \epsilon, \mathcal{E}$ and $\alpha$ are independent of $d$ and $h$ and are given in Section 4.1.

Proof. The proof is similar as for the Euler discretization and is given in Section 5.2.
Next, consider the Markov chain $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)_{k \in \mathbb{N}}$ given by the UBU-discretization scheme.
Theorem 6 (Contraction for the UBU discretization scheme). Let $U$ satisfy Assumption 1. Let $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{d}$. Let $h>0$ and $\gamma>0$ satisfy (15) and (14). Then for any $k \in \mathbb{N}$ it holds

$$
\begin{equation*}
\mathbb{E}\left[\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right] \leq \mathbf{C}(1-c h)^{k} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \tag{18}
\end{equation*}
$$

where the contraction rate $c$ is given by (17) and the additional constant $C>0$ is given by

$$
\begin{equation*}
\mathbf{C}=\left(1+\frac{\gamma h}{16}\right) \max \left((1+\alpha \gamma h / 2)^{2}, 1+\gamma h \max \left(1, L_{K} \gamma^{-2}\right)\right) \tag{19}
\end{equation*}
$$

Proof. The proof is given in Section 5.2.
Similarly to the Euler scheme, we obtain convergence in $L^{1}$-Wasserstein distance for the UBU scheme due to the equivalence of the distance $\rho$ and the Euclidean distance. Consider two probability measures $\mu_{0}, \nu_{0}$ on $\mathbb{R}^{2 d}$. Let $\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right)$ and $\left(\mathbf{X}_{0}^{\prime}, \mathbf{V}_{0}^{\prime}\right)$ be distributed with respect to $\mu_{0}$ and $\nu_{0}$, respectively. Then, we denote by $\mu_{k}=\operatorname{Law}\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)$ and $\nu_{k}=\operatorname{Law}\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)$ the laws of the discretised kinetic Langevin sampler after $k \in \mathbb{N}$ UBU-steps, respectively.

Corollary 7 (Convergence in $L^{1}$-Wasserstein distance). Suppose Assumption 1, (14) and (15) hold. Then, for $k \in \mathbb{N}$

$$
\begin{aligned}
& \mathcal{W}_{\rho}\left(\mu_{k}, \nu_{k}\right) \leq \mathbf{C} \exp (-c k h) \mathcal{W}_{\rho}\left(\mu_{0}, \nu_{0}\right), \\
& \mathcal{W}_{1}\left(\mu_{k}, \nu_{k}\right) \leq \mathbf{C M} \exp (-c k h) \mathcal{W}_{1}\left(\mu_{0}, \nu_{0}\right),
\end{aligned}
$$

where $c$ is given by (10), $\mathbf{C}>0$ is given in (19), and $\mathbf{M}$ is given in (30). Moreover, existence of a unique invariant measure $\mu_{h, \infty}$ and convergence towards its holds, i.e., for $k \in \mathbb{N}$

$$
\begin{aligned}
& \mathcal{W}_{\rho}\left(\mu_{k}, \mu_{h, \infty}\right) \leq \mathbf{C} \exp (-c k h) \mathcal{W}_{\rho}\left(\mu_{0}, \mu_{h, \infty}\right) \\
& \mathcal{W}_{1}\left(\mu_{k}, \mu_{h, \infty}\right) \leq \mathbf{C M} \exp (-c k h) \mathcal{W}_{1}\left(\mu_{0}, \mu_{h, \infty}\right)
\end{aligned}
$$

Remark 6. As for the Euler scheme, we observe that in the strong convex case, i.e., $R=0$, the rate $c$ reduces to $c=\min \left(\kappa \gamma^{-1} / 24, \gamma / 64\right)$ and the constant $C$ is given by $C=1+$ $2 \gamma h \max \left(1, L_{K} \gamma^{-2}\right)$. Assuming that $L_{G}$ satisfies $L_{G} \leq \sqrt{3 / 104} \kappa$ and choosing $\gamma=\sqrt{3 / 8 \kappa}$, we obtain a contraction rate of order $\sqrt{\kappa}$. Note that compared to the convergence result of the continuous Langevin dynamics [59, Remark 2], we only loose a constant prefactor in the contraction rate and in the condition for the smallness of the perturbation to the Gaussian case.

### 3.4. Assumptions for error analysis

Assumption 1 is the only condition necessary for the convergence analysis and order one bias estimates for the numerical schemes we consider. However to establish higher-order bounds with an improved dimension dependence we introduce Assumptions 2 and 3 and some motivating examples. We will state the main results in the paper in cases where each of the Assumptions is satisfied.
Assumption 2. The potential $U: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is three times continuously differentiable and there exists $L_{1}>0$ such that for all $x, y \in \mathbb{R}^{d}$,

$$
\left\|\nabla^{2} U(x)-\nabla^{2} U(y)\right\| \leq L_{1}\|x-y\|
$$

this implies that

$$
\left\|\nabla^{3} U(x)\left[v, v^{\prime}\right]\right\| \leq L_{1}\|v\|\left\|v^{\prime}\right\|
$$

which was used in [58].
Assumption 2 is not strong enough to achieve an improved dimension dependence, which is observed in many applications of interest (see [18]). A stronger assumption can be used, specifically, the strongly Hessian Lipschitz property introduced in [20] and used in [56], which uses the following tensor norm.
Definition 8. For $A \in \mathbb{R}^{d \times d \times d}$, let us define

$$
\|A\|_{\{1,2\}\{3\}}=\sup _{x \in \mathbb{R}^{d \times d}, y \in \mathbb{R}^{d}}\left\{\sum_{i, j, k=1}^{d} A_{i j k} x_{i j} y_{k} \mid \sum_{i, j=1}^{d} x_{i j}^{2} \leq 1, \sum_{k=1}^{d} y_{k}^{2} \leq 1\right\}
$$

Assumption 3. $U: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is three times continuously differentiable and strongly Hessian Lipschitz if there exists a $L_{1}^{s}>0$ such that

$$
\left\|\nabla^{3} U(x)\right\|_{\{1,2\}\{3\}} \leq L_{1}^{s}
$$

for all $x \in \mathbb{R}^{d}$.
It is easy to show that Assumption 2 is equivalent to a uniform bound on the matrix norm defined by

$$
\left\|\nabla^{3} U(x)\right\|_{\{1\},\{2\},\{3\}}:=\sup \left\{\sum_{i, j, k=1}^{d}\left[\nabla^{3} U(x)\right]_{i j k} x_{i} y_{j} z_{k} \mid \sum_{i} x_{i}^{2} \leq 1, \sum_{j} y_{j}^{2} \leq 1, \sum_{k} z_{k}^{2} \leq 1\right\}
$$

for all $x \in \mathbb{R}^{d}$. Due to [56, Lemma 8] we have the following equivalency relationship of the norms

$$
\|\cdot\|_{\{1\},\{2\},\{3\}} \leq\|\cdot\|_{\{1,2\},\{3\}} \leq \sqrt{d}\|\cdot\|_{\{1\},\{2\},\{3\}} .
$$

Remark 7 (Examples). It is easy to show that Assumption 3 is satisfied without additional dimension dependency for product distributions as the tensor $\nabla^{3} U(\cdot)$ is diagonal.

In $[20$, Section 6$]$ they introduce a wide range of applications which have a small strongly Hessian Lipschitz constant including Bayesian statistical models such as Bayesian ridge regression and generalised linear models. They also show logistic regression problems and two-layer neural networks satisfy Assumption 3 with a small constant. The two-layer neural network problem is of particular interest as an application of interacting particle system-based methods [50, 36, 12].

In the case of interacting particle systems, examples of interaction potential taken from Molecular dynamics problems which satisfy Assumption 2 are the Morse potential and the harmonic bonding potential [41, Chapter 1].

### 3.5. Complexity guarantees for the $U B U$ scheme

Under the respective assumptions we bound the distanc between the invariant measure $\mu_{h, \infty}$ of the UBU scheme and the target measure $\mu_{\infty}$.

Theorem 9. Let $U$ satisfy Assumption 1 and let $h>0$ satisfy (15) and $\gamma>0$ satisfy (14) then

$$
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \leq \frac{15 \mathbf{C} h \sqrt{d}}{c}\left(\gamma^{-1} L+\alpha\left(5 L+\gamma L^{1 / 2}\right) h\right),
$$

if $U$ satisfies additionally Assumption 2 then

$$
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \leq \frac{12 \mathbf{C} h^{2} \sqrt{d}}{c}\left(2 \gamma^{-1}\left(L_{1} \sqrt{d}+L^{3 / 2}+\gamma L\right)+\alpha\left(5 L+\gamma L^{1 / 2}\right)\right),
$$

and further if $U$ satisfies Assumption 3 then

$$
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \leq \frac{12 \mathbf{C} h^{2} \sqrt{d}}{c}\left(2 \gamma^{-1}\left(L_{1}^{s}+L^{3 / 2}+\gamma L\right)+\alpha\left(5 L+\gamma L^{1 / 2}\right)\right),
$$

for distance function $\rho$ given in Section 4.1, contraction rate c defined by (17) and preconstant C defined by (19).

Let $\nu_{k}$ denote the law of the UBU-scheme after $k$ steps with initial distribution $\nu_{0}$ on $\mathbb{R}^{2 d}$. By the previous result, we bound the distance between $\nu_{k}$ and $\mu_{\infty}$.

Theorem 10. Let $U$ satisfy Assumption 1 and let $h>0$ satisfy (15) and $\gamma>0$ satisfy (14) then

$$
\mathcal{W}_{1}\left(\nu_{k}, \mu_{h, \infty}\right) \leq \frac{15 \mathbf{C N} h \sqrt{d}}{c}\left(\gamma^{-1} L+\alpha\left(5 L+\gamma L^{1 / 2}\right) h\right)+\mathbf{M C} e^{-c h k} \mathcal{W}_{1}\left(\nu_{0}, \mu_{h, \infty}\right)
$$

if $U$ satisfies additionally Assumption 2 then

$$
\begin{aligned}
\mathcal{W}_{1}\left(\nu_{k}, \mu_{h, \infty}\right) & \leq \frac{12 \mathbf{C N} h^{2} \sqrt{d}}{c}\left(2 \gamma^{-1}\left(L_{1} \sqrt{d}+L^{3 / 2}+\gamma L\right)+\alpha\left(5 L+\gamma L^{1 / 2}\right)\right) \\
& +\mathbf{M C} e^{-c h k} \mathcal{W}_{1}\left(\nu_{0}, \mu_{h, \infty}\right)
\end{aligned}
$$

and further if $U$ satisfies Assumption 3 then

$$
\begin{aligned}
\mathcal{W}_{1}\left(\nu_{k}, \mu_{h, \infty}\right) & \leq \frac{12 \mathbf{C N} h^{2} \sqrt{d}}{c}\left(2 \gamma^{-1}\left(L_{1}^{s}+L^{3 / 2}+\gamma L\right)+\alpha\left(5 L+\gamma L^{1 / 2}\right)\right) \\
& +\mathbf{M C} e^{-c h k} \mathcal{W}_{1}\left(\nu_{0}, \mu_{h, \infty}\right)
\end{aligned}
$$

for distance function $\rho$ given in Section 4.1, contraction rate c defined by (17), the preconstants $\mathbf{C}, \mathbf{M}$ and $\mathbf{N}$ are defined by (19),(30) and (31) respectively.

Remark 8 (Complexity guarantees). We establish the same complexity guarantees as the Euler scheme when we do not have additional smoothness (only Assumption 1 holds). When Assumption 2 holds by the same reasoning as Remark 4, if we choose $h \propto \sqrt{\epsilon / d}$ and the number of steps $k$ of order $k \propto \log (\Delta(0) / \varepsilon) /(c h)$, where $\Delta(0)=\mathcal{W}_{1}\left(\mu_{h, \infty}, \nu_{0}\right)$. We then achieve a $\varepsilon$-accuracy in the order of $\sqrt{d / \epsilon}$ steps. If additionally Assumption 3 holds we can achieve $\varepsilon$-accuracy in an improved order of $d^{1 / 4} / \sqrt{\epsilon}$ steps.
Remark 9 (Particle model and propagation of chaos for the UBU scheme). As for the Euler scheme (see Remark 5), we can also get bounds on the strong accuracy for the UBU scheme applied to the particle model. Together with the propagation of chaos result given in [59, Theorem 17], it is possible to bound under the assumptions in Theorem 9 and a smallness assumption on the interaction potential the distance between the law $\mu_{k}^{N}$ of the particle system with $N$ after $k$-UBU steps and the measure $\mu_{*}$ given in (13) by

$$
\mathcal{W}_{\ell_{1}^{N}}\left(\mu_{k}^{N}, \mu_{*}^{\otimes N}\right) \leq C\left(e^{-c h k} \mathcal{W}_{1}\left(\mu_{0}, \mu_{*}\right)+\sqrt{d} h^{2}+N^{-1 / 2}\right)
$$

for some constant $C>0$ which is independent of $N, d$ and $h$ and rate $c>0$ which is up to a constant factor of the same form as the rate in (17). We note that this bound has a better order in $h$ compared to the complexity bounds of nonlinear HMC given in [12].

### 3.6. Numerical illustration of the coupling

We implement synchronous and reflection coupling as defined in the analysis (see Section 4.3) for two model problems and the BU scheme (and UBU equivalently). These model problems were also considered in $[7,11]$ and contour plots of their respective potentials are given in Figures 2 and 3. First of which is the banana-shaped potential, which is defined for $(x, y) \in \mathbb{R}^{2}$ by

$$
U(x, y)=(1-x)^{2}+10\left(y-x^{2}\right)^{2}
$$

which is unimodal, but has a very flat minima and does not satisfy the strong-convexity assumption. The second is a 10-mode Gaussian mixture model where each of the ten Gaussian distributions has standard deviation $\sigma=0.5$ and mean given as in [45, Table 1].

In Figure 2 and Figure 3 the contraction properties are illustrated for the two model cases under synchronous and reflection coupling. Interestingly we observe very slow convergence for

Fig 2: Banana potential: Bold lines on the plot are where reflection coupling is used and dashed lines are where synchronous coupling is used. Initializing two trajectories coupled using synchronous coupling and our reflection coupling construction for the BU scheme initialized at $[4,16]$ and $[-4,16]$ respectively for the banana potential model. Plotting the average distance between the trajectories versus time (number of iterations multiplied by stepsize) where we have averaged the results over 100,000 independent runs. Left: Contour of basin of potential. Middle: Convergence of couplings. Right: Convergence of couplings on log-scale.

Fig 3: Gaussian Mixture Model: Bold lines on the plot are where reflection coupling is used and dashed lines are where synchronous coupling is used. Initializing two trajectories coupled using synchronous coupling and our reflection coupling construction for the BU scheme initialized at $[1,1]$ and $[9,9]$ respectively for the Gaussian mixture model. Plotting the average distance between the trajectories versus time (number of iterations multiplied by stepsize) where we have averaged the results over 100,000 independent runs. Left: Contour of potential. Middle: Convergence of couplings. Right: Convergence of couplings on log-scale.
synchronous coupling on the Banana potential model for small values of the friction parameter, in particular when the coupled chains are close together in the very flat basin. However, when reflection coupling is used this is not the case. The initial bump in 2 corresponds to the additional prefactor we have in the convergence results in Wasserstein distance with respect to the Euclidean distance. After this initial phase, we exhibit exponential convergence, which is illustrated in Figure 2 and 3 on the log-scale, we remark that at small distances on the log-scale the estimators have very high relative variance, hence noise is present even after 100,000 independent runs.

## 4. Coupling and distance construction

### 4.1. Distance function

As in the construction of the distance function in [59, Section 4], we consider two metrics $r_{l}, r_{s}: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ given by

$$
\begin{aligned}
r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)^{2} & :=\gamma^{-2}\left(x-x^{\prime}\right)^{T} K\left(x-x^{\prime}\right)+\frac{1}{2}\left|(1-2 \tau)\left(x-x^{\prime}\right)+\gamma^{-1}\left(v-v^{\prime}\right)\right|^{2} \\
& +\frac{1}{2} \gamma^{-2}\left|v-v^{\prime}\right|^{2}
\end{aligned}
$$

and

$$
r_{s}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right):=\alpha\left|x-x^{\prime}\right|+\left|x-x+\gamma^{-1}\left(v-v^{\prime}\right)\right|
$$

for $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{2 d}$, where the constant $\tau$ and $\alpha$ are given by

$$
\begin{align*}
\tau & :=\min \left(1 / 8, \gamma^{-2} \kappa / 2-\gamma^{-4} L_{G}^{2}\right) \quad \text { and }  \tag{20}\\
\alpha & :=2 L \gamma^{-2} \tag{21}
\end{align*}
$$

The matrix $K$ is a positive-definite matrix with smallest eigenvalue $\kappa>0$ and is given by splitting $\nabla U(x)=K x+\nabla G(x)$, where $G$ is a convex function outside a ball of radius $R$. Before constructing the metric $\rho: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ we note that the distances $r_{l}$ and $r_{s}$ are equivalent, i.e., it holds

$$
\begin{equation*}
2 \epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \leq r_{s}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \leq \mathcal{E}^{-1} r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \tag{22}
\end{equation*}
$$

with

$$
\begin{align*}
\epsilon & :=\frac{1}{2} \min \left(1, \frac{2 \alpha}{3 \sqrt{\kappa} \gamma^{-1}}, \alpha\right)  \tag{23}\\
\mathcal{E} & :=\min \left(\frac{\sqrt{L_{K}} \gamma^{-1}}{\sqrt{8} \alpha}, \frac{1}{2}\right) \tag{24}
\end{align*}
$$

Define

$$
\Delta\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right):=r_{s}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)-\epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)
$$

for $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{2 d}$ and

$$
D_{\mathcal{K}}:=\sup _{\substack{\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \in \mathbb{R}^{4 d} \\\left(x-x^{\prime}, v-v^{\prime}\right) \in \mathcal{K}}} \Delta\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)
$$

where the compact set $\mathcal{K}$ on $\mathbb{R}^{2 d}$ is given by

$$
\mathcal{K}:=\left\{(z, w) \in \mathbb{R}^{2 d}: \kappa \gamma^{-2}|z|^{2}+(1 / 2)\left|z+\gamma^{-1} w\right|^{2}+(1 / 2)\left|\gamma^{-1} w\right|^{2} \leq \mathcal{R}\right\}
$$

with

$$
\begin{equation*}
\mathcal{R}:=\tau^{-1} L_{G} R^{2} \gamma^{-2} \tag{25}
\end{equation*}
$$

Further, we define the constant $R_{1}$ by

$$
R_{1}:=\sup _{\substack{\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right): \\ \Delta\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \leq D_{\mathcal{K}}}} r_{s}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)
$$

Then, we define the metric $\rho: \mathbb{R}^{2 d} \times \mathbb{R}^{2 d} \rightarrow[0, \infty)$ by

$$
\begin{equation*}
\rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)=f\left(\Delta\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \wedge D_{\mathcal{K}}+\epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)\right) \tag{26}
\end{equation*}
$$

for $(x, v),\left(x^{\prime}, v^{\prime}\right) \in \mathbb{R}^{2 d}$. The function $f$ is an increasing concave function with $f(0)=0$ and is defined by

$$
\begin{equation*}
f(r)=\int_{0}^{r} \phi(s) \psi(s) \mathrm{d} s \tag{27}
\end{equation*}
$$

where

$$
\begin{array}{ll}
\phi(s)=\exp \left(-128 \alpha \gamma^{2} \frac{\left(s \wedge R_{1}\right)^{2}}{2}\right) & \Phi(s)=\int_{0}^{s} \phi(x) \mathrm{d} x \\
\psi(s)=1-\frac{\hat{c}}{2} \gamma \int_{0}^{s \wedge R_{1}} \Phi(x) \phi(x)^{-1} \mathrm{~d} x & \hat{c}=\frac{1}{\gamma \int_{0}^{R_{1}} \Phi(s) \phi(s)^{-1} \mathrm{~d} s}
\end{array}
$$

We note that for $r \in\left[0, R_{1}\right)$, the function $f$ satisfies

$$
\begin{equation*}
f^{\prime}(r) \alpha \gamma r+4 \gamma^{-1} f^{\prime \prime}(r) \leq-2 \hat{c} f(r) \tag{28}
\end{equation*}
$$

Further, for all $r \geq 0$

$$
f^{\prime}\left(R_{1}\right) r \leq f^{\prime}(r) r \leq f(r) \leq \Phi(r) \leq r
$$

since $\psi(r) \in[1 / 2,1]$. We refer to [59] where a proof that $\rho$ defines indeed a metric is given. In particular it holds

$$
\begin{equation*}
\left|(x, v)-\left(x^{\prime}, v^{\prime}\right)\right| \leq \mathbf{N} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \leq \mathbf{M}\left|(x, v)-\left(x^{\prime}, v^{\prime}\right)\right| \tag{29}
\end{equation*}
$$

with

$$
\begin{align*}
& \mathbf{M}=f^{\prime}\left(R_{1}\right)^{-1} \frac{2 \max (\gamma(1+\alpha), 1)}{\epsilon \min (\sqrt{2 \kappa}, 1)}  \tag{30}\\
& \mathbf{N}=f^{\prime}\left(R_{1}\right)^{-1} \frac{\gamma}{\epsilon \min (\sqrt{\kappa}, \sqrt{1 / 2})} \tag{31}
\end{align*}
$$

Further, observe that in the strong convex case, i.e., $R=0$, the construction of the distances reduces to $\rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)=r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)$.

### 4.2. Coupling construction for the Euler scheme

Next, we define the coupling by using the idea of the coupling construction from [7]. Consider two states $(x, v)$ and $\left(x^{\prime}, v^{\prime}\right)$. We define the next coupling step of two copies given by (2) depending whether the two current positions $(x, v)$ and $\left(x^{\prime}, v^{\prime}\right)$ are close to each other or far apart.

In particular, the chains are coupled through the sequence of random variables $\left(\xi_{k}, \xi_{k}^{\prime}\right)_{k}$ on a common probability space and which satisfy $\xi_{k}, \xi_{k}^{\prime} \sim \mathcal{N}\left(0, I_{d}\right)$ for all $k \in \mathbb{N}$.

Synchronous coupling: Given $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right) \in \mathbb{R}^{2 d}$. If

$$
D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \leq r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)
$$

i.e., if the two states are far apart, we take the same random variables $\xi_{k+1}=\xi_{k+1}^{\prime}$ and the next step $\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right)$ is given by

$$
\begin{aligned}
& \left\{\begin{array}{l}
\mathbf{X}_{k+1}=\mathbf{X}_{k}+h \mathbf{V}_{k} \\
\mathbf{V}_{k+1}=\mathbf{V}_{k}-h \nabla U\left(\mathbf{X}_{k}\right)-h \gamma \mathbf{V}_{k}+\sqrt{2 \gamma h} \xi_{k+1}, \\
\left\{\begin{array}{l}
\mathbf{X}_{k+1}^{\prime}=\mathbf{X}_{k}^{\prime}+h \mathbf{V}_{k}^{\prime} \\
\mathbf{V}_{k+1}^{\prime}=\mathbf{V}_{k}^{\prime}-h \nabla U\left(\mathbf{X}_{k}^{\prime}\right)-h \gamma \mathbf{V}_{k}^{\prime}+\sqrt{2 \gamma h} \xi_{k+1}
\end{array}\right.
\end{array} . \begin{array}{l}
\end{array}\right.
\end{aligned}
$$

Contractive coupling: If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)>r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)$, then let $\xi_{k+1}$ be a normally distributed random variable. Let $\mathcal{U}$ be an independent uniformly distributed random variable on $[0,1]$ and $\beta$ be given by

$$
\begin{equation*}
\beta=\frac{1}{\sqrt{2 \gamma^{-1} h}} \tag{32}
\end{equation*}
$$

We define $\xi_{k+1}^{\prime}$ by

$$
\xi_{k+1}^{\prime}= \begin{cases}\xi_{k+1}+\beta q_{k} & \text { if } \mathcal{U} \leq \frac{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}+\beta\left|q_{k}\right|\right)}{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}\right)},  \tag{33}\\ \xi_{k+1}-2\left(e_{k} \cdot \xi_{k+1}\right) e_{k} & \text { otherwise }\end{cases}
$$

where $q_{k}=\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}+\gamma^{-1}\left(\mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}\right), e_{k}=q_{k} /\left|q_{k}\right|$, and $\varphi_{0,1}$ denotes the density of the standard normal distribution. We set $\hat{q}_{k}=\beta q_{k}$ and

$$
\Xi_{k+1}=\xi_{k+1}-\xi_{k+1}^{\prime}= \begin{cases}-\hat{q}_{k} & \text { if } \mathcal{U} \leq \frac{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}+\beta\left|q_{k}\right|\right)}{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}\right)}, \\ 2\left(e_{k} \cdot \xi_{k+1}\right) e_{k} & \text { otherwise }\end{cases}
$$

Note that on the line $q_{k}=0$ this coupling simplifies to a synchronous coupling. This corresponds to the coupling for the time-continuous Langevin dynamics in [30, 59]. Moreover, for $h \rightarrow 0$ the above-constructed coupling converges to the one in [30,59]. Moreover, if $q_{k} \neq 0$, it holds $\xi_{k+1}-\xi_{k+1}^{\prime}=-\beta q_{k}$ with maximal probability. Otherwise, we consider a reflection coupling, which is reflected at the hyperspace $q_{k}=0$. We note that this indeed defines a coupling, see [7, Section 2.3.2.].

### 4.3. Coupling construction for the BU scheme

Similarly, the construction for the coupling for the BU scheme relies on the idea of the coupling from [19]. Consider two states $(x, v)$ and $\left(x^{\prime}, v^{\prime}\right)$. The coupled chain $\left(\mathbf{X}_{k}, \mathbf{V}_{k}, \mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)_{k}$ of two copies of the BU scheme is given by coupling the sequence of random variables $\left(\xi_{k}^{(1)}, \xi_{k}^{(2)}\right)_{k}$ and $\left(\xi_{k}^{(1)^{\prime}}, \xi_{k}^{(2)^{\prime}}\right)_{k}$ on a common probability space such that $\left(\xi_{k}^{(1)}, \xi_{k}^{(2)}\right),\left(\xi_{k}^{(1)^{\prime}}, \xi_{k}^{(2)^{\prime}}\right) \sim \mathcal{N}\left(0_{2 d}, I_{2 d}\right)$ for all $k \in \mathbb{N}$.

Given $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right) \in \mathbb{R}^{2 d}$. Let $\left(\xi_{k+1}^{(1)}, \xi_{k+1}^{(2)}\right) \sim \mathcal{N}\left(0_{2 d}, I_{2 d}\right)$. If

$$
D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \leq r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right),
$$

we couple the random variables synchronously, i.e., we set $\xi_{k+1}^{(1)^{\prime}}=\xi_{k+1}^{(1)}$ and $\xi_{k+1}^{(2)^{\prime}}=\xi_{k+1}^{(2)}$. Hence, for $Z_{k}=\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}$ and $W_{k}=\mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}$ it holds

$$
\left\{\begin{array}{l}
Z_{k+1}=Z_{k}+\frac{1-\exp (-\gamma h)}{\gamma} W_{k}-\frac{1-\eta}{\gamma} h\left(\nabla U\left(\mathbf{X}_{k}\right)-\nabla U\left(\mathbf{X}_{k}^{\prime}\right)\right) \\
W_{k+1}=\exp (-\gamma h) W_{k}-h \exp (-\gamma h)\left(\nabla U\left(\mathbf{X}_{k}\right)-\nabla U\left(\mathbf{X}_{k}^{\prime}\right) .\right.
\end{array}\right.
$$

If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)>r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)$, we set $\xi_{k+1}^{(2)^{\prime}}=\xi_{k+1}^{(2)}$ and construct $\xi_{k+1}^{(1)^{\prime}}$ in the following way: Let $\mathcal{U} \sim \operatorname{Unif}[0,1]$ be an independent uniformly distributed random variable and let $\beta$ be given by (32). We define $\xi^{(1)^{\prime}}$ as in (33), i.e.,

$$
\xi_{k+1}^{(1)^{\prime}}= \begin{cases}\xi_{k+1}^{(1)}+\beta q_{k} & \text { if } \mathcal{U} \leq \frac{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}+\beta\left|q_{k}\right|\right)}{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}\right)}  \tag{34}\\ \xi_{k+1}^{(1)}-2\left(e_{k} \cdot \xi_{k+1}^{(1)}\right) e_{k} & \text { otherwise }\end{cases}
$$

where $q_{k}=\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}+\gamma^{-1}\left(\mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}\right), e_{k}=q_{k} /\left|q_{k}\right|$, and $\varphi_{0,1}$ denotes the density of the standard normal distribution. Further, as for the Euler scheme, we set $\hat{q}_{k}=\beta q_{k}$ and the difference of $\xi_{k+1}^{(1)}$ and $\xi_{k+1}^{(1)^{\prime}}$ satisfies

$$
\Xi_{k+1}=\xi_{k+1}^{(1)}-\xi_{k+1}^{(1)^{\prime}}= \begin{cases}-\hat{q}_{k} & \text { if } \mathcal{U} \leq \frac{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}^{(1)}+\beta\left|q_{k}\right|\right)}{\varphi_{0,1}\left(e_{k} \cdot \xi_{k+1}^{(1)}\right)} \\ 2\left(e_{k} \cdot \xi_{k+1}^{(1)}\right) e_{k} & \text { otherwise }\end{cases}
$$

This construction defines a coupling, see [7, Section 2.3.2.].

## 5. Proofs

### 5.1. Euler-Maruyama

To prove Theorem 1, we first show local contraction for the distance $r_{l}$ if the distance is sufficiently large.
Proposition 11. Let the potential $U$ be of the form $U:=x^{T} K x+G(x)$, where the symmetric and positive definite matrix $K$ satisfies $\kappa I_{d} \prec K \prec L_{K} I_{d}$ and $\nabla G$ is convex for all $x, y \in \mathbb{R}^{d}$ such that $|x-y|>R$, now consider two iterates of the Euler-Maruyama scheme $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)_{k \in \mathbb{N}}$ and $\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)_{k \in \mathbb{N}}$ with synchronously coupled noise increments and metric $r_{l}$ between the iterates. If $r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \geq \mathcal{R}$ at iteration $k \in \mathbb{N}$ with $\mathcal{R}$ given in (25), $h<\min \left\{\frac{\gamma}{32 L_{K}}, \frac{1}{8 \gamma}\right\}$ and $L_{G} \gamma^{-2} \leq \kappa /\left(16 L_{G}\right)$ we have that

$$
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) \leq(1-\tau \gamma h) r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)
$$

where $\tau=\min \left\{\frac{\kappa}{4 \gamma^{2}}, \frac{1}{8}\right\}$. If $R=0, \mathcal{R}=0$ and the restriction on $\gamma$ improves to $\left(4+\frac{3}{4}\right) L_{G} \gamma^{-2} \leq$ 1.

Due to controlling the additional discretization error the bound on $\gamma$ is worse than the bound in the continuous dynamics given in [59]. For $h$ tending to zero, we can actually recover the condition for $\gamma$ from the continuous dynamics.

Proof. We have that

$$
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right)=\left(Z_{k}, W_{k}\right) P^{T} M P \cdot\left(Z_{k}, W_{k}\right),
$$

where

$$
M=\left(\begin{array}{cc}
\gamma^{-2} K+(1-2 \tau)^{2} / 2 I_{d} & (1-2 \tau) / 2 \gamma I_{d} \\
(1-2 \tau) / 2 \gamma I_{d} & \gamma^{-2} I_{d}
\end{array}\right), \text { and } P=\left(\begin{array}{cc}
I_{d} & h I_{d} \\
-h(K+Q) & (1-\gamma h) I_{d}
\end{array}\right) .
$$

The matrix $K$ is given by the quadratic term in the potential and $Q$ is defined by

$$
Q=\int_{t=0}^{1} \nabla^{2} G\left(\mathbf{X}_{k}+t\left(\mathbf{X}_{k}^{\prime}-\mathbf{X}_{k}\right)\right) d t
$$

where $G$ is the non-quadratic term in the potential and $Q \succ 0$ for $\left|\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}\right|>R$ and $L_{G} I_{d} \succ Q \succ-L_{G} I_{d}$ otherwise. It holds

$$
\begin{aligned}
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) & =r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \\
& +\left(Z_{k}, W_{k}\right)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1}\right)\left(Z_{k}, W_{k}\right)
\end{aligned}
$$

with

$$
P_{1}=\left(\begin{array}{cc}
0 & I_{d} \\
-K-Q & -\gamma I_{d}
\end{array}\right) .
$$

It is sufficient to show that for all $(z, w) \in \mathbb{R}^{2 d}$ with $r_{l}^{2}((z, w)) \geq \mathcal{R},(z, w)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+\right.$ $\left.h^{2} P_{1}^{T} M P_{1}\right)(z, w) \leq-\gamma \tau h(z, w)^{T} M(z, w)$. It holds

$$
\begin{aligned}
h\left(M P_{1}+P_{1}^{T} M\right) & =h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q) & -\gamma^{-2} Q-\tau(1-2 \tau) I_{d} \\
-\gamma^{-2} Q-\tau(1-2 \tau) I_{d} & \left(-2 \tau \gamma^{-1}-\gamma^{-1}\right) I_{d}
\end{array}\right) \\
& \prec h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q)+2 \gamma^{-3} Q^{2} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & \left(-2 \tau \gamma^{-1}-\frac{\gamma^{-1}}{2}\right) I_{d}
\end{array}\right),
\end{aligned}
$$

since for all $(z, w) \in \mathbb{R}^{2 d}, z^{T}\left(-Q \gamma^{-2}\right) w \leq \gamma^{-3} z^{T} Q^{2} z+1 / 4 \gamma^{-1}|w|^{2}$ and $w^{T}\left(-Q \gamma^{-2}\right) z \leq$ $\gamma^{-3} z^{T} Q^{2} z+1 / 4 \gamma^{-1}|w|^{2}$. Further,

$$
\begin{aligned}
h^{2} P_{1}^{T} M P_{1} & =h^{2}\left(\begin{array}{cc}
(K+Q)^{2} \gamma^{-2} & \frac{-1-\tau}{\gamma}(K+Q) \\
\frac{-1-\tau}{\gamma}(K+Q) & K \gamma^{-2}+\frac{1+4 \tau^{2}}{2} I_{d}
\end{array}\right) \\
& \prec h^{2}\left(\begin{array}{cc}
(K+Q)^{2} \gamma^{-2}+\frac{1}{2 \gamma^{2}}(K+Q)^{2} & 0 \\
0 & K \gamma^{-2}+\frac{3+4 \tau^{2}}{2} I_{d}
\end{array}\right) \\
& \prec h^{2}\left(\begin{array}{cc}
(3 / 2)(K+Q)^{2} \gamma^{-2} & 0 \\
0 & K \gamma^{-2}+2 I_{d}
\end{array}\right),
\end{aligned}
$$

since $z^{T} \frac{-1-\tau}{\gamma}(K+Q) w \leq \frac{1}{2 \gamma^{2}} z^{T}(K+Q)^{2} z+\frac{(1+\tau)^{2}}{2}|w|^{2}$ and $\tau \leq 1 / 8$. Further, we observe that $h^{2}(3 / 2)(K+Q)^{2} \prec h^{2}\left(3 K^{2}+3 Q^{2}\right) \prec h^{2}\left(3 L_{K} K+3 Q^{2}\right)$, where we used in the second step that $K$ is symmetric and positive definite and hence we can take the square root of $K$. Putting the previous estimates together, we obtain

$$
\begin{aligned}
& h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1} \\
& \prec h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q)+2 \gamma^{-3} Q^{2} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & \left(-2 \tau \gamma^{-1}-\frac{\gamma^{-1}}{2}\right) I_{d}
\end{array}\right)+h^{2}\left(\begin{array}{cc}
\frac{3 L_{K}}{\gamma^{2}} K+\frac{3}{\gamma^{2}} Q^{2} & 0 \\
0 & \frac{K}{\gamma^{2}}+2 I_{d}
\end{array}\right) .
\end{aligned}
$$

By the condition on $h$ it holds $h^{2} \frac{3 L_{K}}{\gamma^{2}} K \prec \frac{3(1-4 \tau)}{64 \gamma} K, h\left(L_{K} \gamma^{-2}+2\right) \leq \frac{1}{2 \gamma}$ and $3 h L_{G}^{2} \gamma^{-2} \leq$ $\frac{3}{8} \gamma^{-3} L_{G}^{2}$, and hence

$$
\begin{aligned}
& h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1} \\
& \prec h\left(\begin{array}{cc}
\frac{(1-2 \tau)}{\gamma}(-K-Q)+\frac{3(1-4 \tau)}{64 \gamma} K+\left(2+\frac{3}{8}\right) \gamma^{-3} L_{G}^{2} I_{d} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & -2 \tau \gamma^{-1} I_{d}
\end{array}\right) .
\end{aligned}
$$

By assumption on $G$ and $\gamma$ and the choice of $\tau$, we observe

$$
\frac{(1-2 \tau)}{\gamma} z^{T}(-Q) z \leq \frac{(1-2 \tau)}{\gamma} L_{G} \mathbb{1}_{|z| \leq R}|z|^{2} \leq L_{G} \gamma^{-1} R^{2}
$$

and

$$
\begin{aligned}
-\frac{61(1-4 \tau)}{64 \gamma} z^{T} K z+\frac{19}{8} \gamma^{-3} L_{G}^{2}|z|^{2} & \leq-\frac{61}{128 \gamma} z^{T} K z+\frac{19}{8} \gamma^{-3} L_{G}^{2}|z|^{2} \\
& \leq-\frac{1}{4 \gamma} \kappa|z|^{2} \leq-2 \tau \gamma \frac{(1-2 \tau)^{2}}{2}
\end{aligned}
$$

Hence,

$$
\begin{aligned}
& (z, w)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1}\right)(z, w) \\
& \leq h(z, w)^{T}\left(\begin{array}{cc}
-2 \tau \gamma\left(\gamma^{-2} K+\frac{(1-2 \tau)^{2}}{2}\right) & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & -2 \tau \gamma^{-1} I_{d}
\end{array}\right)(z, w)+h L_{G} \gamma^{-1} R^{2} \\
& \leq-2 \tau \gamma h(z, w)^{T} M(z, w)+h L_{G} \gamma^{-1} R^{2} \leq-\tau \gamma h(z, w)^{T} M(z, w)
\end{aligned}
$$

where the last step holds by the definition of $\mathcal{R}$. We note that for $R=0, Q$ is positive definite and we can bound directly $-\frac{1-2 \tau}{\gamma} Q+\left(2+\frac{3}{8}\right) \gamma^{-3} Q^{2} \prec 0$, which yields the result.
Proof of Theorem 1. Fix $k \in \mathbb{N}$. Consider $\mathbf{X}_{k}, \mathbf{V}_{k}, \mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime} \in \mathbb{R}^{d}$. We write $Z_{k}=\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}$, $W_{k}=\mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}$ and $q_{k}=Z_{k}+\gamma^{-1} W_{k}$.

Case 1: If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \leq r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)$ holds, then the distance satisfies $\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)=f\left(D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right)$ and we consider a synchronous coupling, i.e., $\xi_{k+1}=\xi_{k+1}^{\prime}$. We observe

$$
\rho_{k+1}:=\rho\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) \leq f\left(D_{\mathcal{K}}+\epsilon r_{l}(k+1)\right),
$$

where we abbreviate $r_{l}(k+1)=r_{l}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right)$. By Proposition 11 it holds

$$
r_{l}(k+1) \leq \sqrt{1-\tau \gamma h} r_{l}(k) \leq\left(1-\frac{\tau \gamma h}{2}\right) r_{l}(k) .
$$

Note that the condition on $h$ follows directly from (8). Hence, since $f$ is concave,

$$
\begin{align*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq \mathbb{E}\left[f\left(D_{\mathcal{K}}+\epsilon r_{l}(k+1)\right)-f\left(D_{\mathcal{K}}+\epsilon r_{l}(k)\right)\right] \\
& \leq f^{\prime}\left(R_{1}\right) \epsilon \mathbb{E}\left[r_{l}(k+1)-r_{l}(k)\right] \leq-f^{\prime}\left(R_{1}\right) c_{1} h r_{l}(k), \tag{35}
\end{align*}
$$

where $c_{1}=\epsilon \tau \gamma / 2$. By (22),

$$
-f^{\prime}\left(R_{1}\right) c_{1} h r_{l}(k) \leq-f^{\prime}\left(R_{1}\right) h \frac{c_{1} r_{l}(k)}{D_{\mathcal{K}}+\epsilon r_{l}(k)} \rho_{k} \leq-f^{\prime}\left(R_{1}\right) c_{1} h \mathcal{E} \rho_{k} .
$$

Case 2: If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)>r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)$, the coupling (33) is applied and $\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)=f\left(r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right)$. To show contraction for small distances, the proof is divided in three steps, i.e., first we consider $\left|Z_{k}\right| \geq 4\left|q_{k}\right|$, then $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right| \geq \sqrt{2 \gamma^{-1} h}$ and finally $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right|<\sqrt{2 \gamma^{-1} h}$.

Step 1: Let $\left|Z_{k}\right| \geq 4\left|q_{k}\right|$. By concavity of $f$, Assumption 1, (2) and (21)

$$
\begin{align*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq \mathbb{E}\left[f\left(r_{s}(k+1)\right)-f\left(r_{s}(k)\right)\right] \leq f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[r_{s}(k+1)-r_{s}(k)\right] \\
& \leq f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[-\frac{h \gamma}{2} \alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|-\left|q_{k}\right|\right] \\
& \leq f^{\prime}\left(r_{s}(k)\right)\left(-\frac{h \gamma}{2} \alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h} \mathbb{E}\left[\left|\hat{q}_{k}+\Xi_{k+1}\right|\right]-\left|q_{k}\right|\right) . \tag{36}
\end{align*}
$$

We set $\hat{r}_{k}=\left|\hat{q}_{k}\right|$. For the term in expectation it holds

$$
\begin{align*}
\mathbb{E}\left[\left|\hat{q}_{k}+\Xi_{k+1}\right|\right] & =\int_{-\hat{r}_{k} / 2}^{\infty}\left|\hat{r}_{k}+2 u\right|\left(\varphi_{0,1}(u)-\varphi_{0,1}\left(u+\hat{r}_{k}\right)\right) \mathrm{d} u \\
& =\int_{-\hat{r}_{k} / 2}^{\infty}\left(\hat{r}_{k}+2 u\right) \varphi_{0,1}(u) \mathrm{d} u-\int_{\hat{r}_{k} / 2}^{\infty}\left(2 u-\hat{r}_{k}\right) \varphi_{0,1}(u) \mathrm{d} u \\
& =\int_{-\hat{r}_{k} / 2}^{\hat{r}_{k} / 2}\left(\hat{r}_{k}+2 u\right) \varphi_{0,1}(u) \mathrm{d} u+\int_{\hat{r}_{k} / 2}^{\infty} 2 \hat{r}_{k} \varphi_{0,1}(u) \mathrm{d} u \\
& =\int_{-\hat{r}_{k} / 2}^{\hat{r}_{k} / 2} \hat{r}_{k} \varphi_{0,1}(u) \mathrm{d} u+\int_{\hat{r}_{k} / 2}^{\infty} 2 \hat{r}_{k} \varphi_{0,1}(u) \mathrm{d} u=\hat{r}_{k}=\left|\hat{q}_{k}\right| . \tag{37}
\end{align*}
$$

Inserting this estimate in (36) and using twice $\left|Z_{k}\right| \geq 4\left|q_{k}\right|$, it holds

$$
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq-f^{\prime}\left(r_{s}(k)\right) \frac{h \gamma}{4} \alpha\left|Z_{k}\right| \leq-f^{\prime}\left(r_{s}(k)\right) \min \left(\frac{h \gamma}{8}, \frac{h \gamma \alpha}{2}\right) r_{s}(k) .
$$

By definition of $f$, it holds

$$
\mathbb{E}\left[\rho_{k+1}\right] \leq\left(1-f^{\prime}\left(R_{1}\right) \min \left(\frac{h \gamma}{8}, \frac{h \gamma \alpha}{2}\right)\right) \rho_{k}
$$

Step 2: Let $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right| \geq \sqrt{2 \gamma^{-1} h}$. By (2), Lipschitz continuity of $\nabla U$, (21), (37) and Taylor expansion

$$
\begin{align*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq \mathbb{E}\left[f\left(\alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|\right)-f\left(\alpha\left|Z_{k}\right|+\left|q_{k}\right|\right)\right] \\
& =f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[\left(\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|-\left|q_{k}\right|\right)\right] \\
& +\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{s}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \\
& =f^{\prime}\left(r_{s}(k)\right)\left(\alpha h \gamma\left|q_{k}\right|\right)+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right], \tag{38}
\end{align*}
$$

where $\bar{r}_{s}(k)=\alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|$. To bound the term in expectation, we split

$$
\begin{aligned}
\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] & =\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] \\
& +\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right],
\end{aligned}
$$

where

$$
\bar{A}=\left\{\Xi_{k+1}=-\hat{q}_{k}\right\} \quad \text { and } \quad \bar{A}^{c}=\left\{\Xi_{k+1} \neq-\hat{q}_{k}\right\}=\left\{\Xi_{k+1}=2\left(e_{k} \cdot \xi_{k+1}\right) e_{k}\right\} .
$$

For the first term we observe

$$
\begin{aligned}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] \\
& =\mathbb{E}\left[\int_{\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right]+\mathbb{E}\left[\int_{r_{s}(k)}^{\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] \\
& \leq \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}}\right] \\
& +\mathbb{E}\left[\frac{\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\bar{r}_{s}(k), \frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}}\right] \\
(39) & \leq \frac{3\left(2 \gamma^{-1} h\right)(1-\alpha \gamma h)^{2}\left|\hat{q}_{k}\right|^{2}}{8} \max _{t \in\left[r_{s}(k)-(1-\alpha h \gamma) / 2\left|q_{k}\right|, r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right] .
\end{aligned}
$$

For the second term we define the set

$$
A^{\prime}=\left\{\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right| \leq\left|q_{k}\right|-\sqrt{2 \gamma^{-1} h}\right\} .
$$

Then,

$$
\begin{aligned}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right] \\
& =\mathbb{E}\left[\int_{r_{s}(k)}^{\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right]+\mathbb{E}\left[\int_{\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right] \\
& \leq \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] \\
& +\mathbb{E}\left[\frac{\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\bar{r}_{s}(k), \frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] \\
(40) & \leq \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] .
\end{aligned}
$$

To bound the second derivative of $f$ in (39) and (40), we observe for $t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]$ the bounds $t \geq(1 / 2) r_{s}(k), \exp \left(-128 \alpha \gamma^{2} \frac{t^{2}}{2}\right) \geq \exp \left(-128 \alpha \gamma^{2} \frac{r_{s}(k)^{2}}{2}\right)$ and $\psi(t) \geq \frac{1}{2} \psi\left(r_{s}(k)\right)$. Further for $s>t, \exp \left(-128 \alpha \gamma^{2} \frac{t^{2}}{2}\right) \geq \exp \left(-128 \alpha \gamma^{2} \frac{s^{2}}{2}\right)$. Hence for $t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]$,

$$
\begin{align*}
f^{\prime \prime}(t) & =-128 \alpha \gamma^{2} t f^{\prime}(t)-\frac{\hat{c} \gamma}{2} \int_{0}^{t} \phi(s) \mathrm{d} s \leq-128 \alpha \gamma^{2} \frac{r_{s}(k)}{2} f^{\prime}(t)-\frac{\hat{c} \gamma}{2} \int_{0}^{\frac{r_{s}(k)}{2}} \phi(s) \mathrm{d} s \\
& \leq-128 \alpha \gamma^{2} \frac{r_{s}(k)}{2} \frac{1}{2} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} \int_{0}^{r_{s}(k)} \phi(s) \mathrm{d} s \\
& \leq-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right) . \tag{41}
\end{align*}
$$

Inserting these estimates in (39) and (40), applying $\left|q_{k}\right| \geq \sqrt{2 \gamma^{-1} h}$ and using that by (8) $\alpha \gamma h \leq 1 / 2$, we obtain

$$
\begin{align*}
\mathbb{E} & {\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] } \\
& =\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right]+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right] \\
& \leq \frac{3\left(2 \gamma^{-1} h\right)}{32}\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right] \\
& +\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] . \tag{42}
\end{align*}
$$

For the expectation in the last term, it holds by (33) and the definition of $A^{\prime}$

$$
\begin{aligned}
& \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] \\
& =\int_{-\infty}^{\infty} \frac{3\left(\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+2 u\right|-\left|q_{k}\right|\right)^{2}}{8} \mathbb{1}_{\left\{\left|\hat{q}_{k}+2 u\right| \leq\left|\hat{q}_{k}\right|-1\right\}}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& =\int_{-\infty}^{-1 / 2} \frac{3\left(\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h} 2 u\right)^{2}}{8}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& =\frac{3 \gamma^{-1} h}{4} \int_{-\infty}^{-1 / 2}\left(\alpha h \gamma\left|\hat{q}_{k}\right|+2 u\right)^{2}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{-\infty}^{-1 / 2}\left(\alpha \sqrt{h \gamma / 2} \gamma R_{1}+2 u\right)^{2}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{-\infty}^{-1 / 2}(1 / 2+2 u)^{2}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{-\infty}^{-1 / 2}(1 / 4)\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u,
\end{aligned}
$$

since by the assumption (8) on $h, \alpha \sqrt{h \gamma / 2} \gamma R_{1} \leq 1 / 2$. Then, by (33)

$$
\begin{aligned}
& \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right]+\frac{3\left(2 \gamma^{-1} h\right)}{32} \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right] \\
& \quad \geq \frac{3 \gamma^{-1} h}{4} \int_{-\infty}^{-1 / 2} \frac{1}{4}(\varphi(u)-\varphi(u+|\hat{q}|))^{+} \mathrm{d} u+\frac{3\left(2 \gamma^{-1} h\right)}{32} \int_{-\infty}^{\infty}(\varphi(u) \wedge \varphi(u+|\hat{q}|) \mathrm{d} u \\
& \quad \geq \frac{3 \gamma^{-1} h}{16} \int_{-\infty}^{-1 / 2} \varphi(u) \mathrm{d} u \geq \frac{9}{160} \gamma^{-1} h
\end{aligned}
$$

Inserting this estimate into the sum of (42) and plugging it back into (38), we obtain

$$
\begin{aligned}
& \mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \\
& \quad \leq f^{\prime}\left(r_{s}(k)\right)\left(\alpha h \gamma\left|q_{k}\right|\right)+\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{2} \frac{1}{2} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \frac{9}{160} \gamma^{-1} h \\
& \quad \leq-\frac{9}{640} \hat{c} h f\left(r_{s}(k)\right) .
\end{aligned}
$$

Step 3: Let $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right|<\sqrt{2 \gamma^{-1} h}$. By (2) and Assumption 1, it holds

$$
\begin{aligned}
& \mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq \mathbb{E}\left[f\left(r_{s}(k+1)\right)-f\left(r_{s}(k)\right)\right] \\
& \left.\quad \leq \mathbb{E}\left[f\left(\alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|\right)\right)-f\left(\alpha\left|Z_{k}\right|+\left|q_{k}\right|\right)\right] \\
& \quad \leq \mathbb{E}\left[f^{\prime}\left(r_{s}(k)\right)\left(\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|-\left|q_{k}\right|\right)\right]+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \\
& \quad \leq f^{\prime}\left(r_{s}(k)\right) \alpha h \gamma\left|q_{k}\right|+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right],
\end{aligned}
$$

where (37) is applied in the last step and $\bar{r}_{s}(k)=\alpha\left|Z_{k}\right|+\alpha h \gamma\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|$. To bound the second term, consider the set

$$
A=\left\{\left|q_{k}\right|+2 \sqrt{2 \gamma^{-1} h} \leq \sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right| \leq\left|q_{k}\right|+6 \sqrt{2 \gamma^{-1} h}\right\}
$$

Then, using the non-positivity of $f^{\prime \prime}$ we bound the expectation by

$$
\begin{aligned}
\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] & \leq \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{A}\right] \\
& \leq \mathbb{E}\left[\int_{\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{A}\right] \\
& \leq \mathbb{E}\left[\frac{\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right), \bar{r}_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{A}\right]
\end{aligned}
$$

By construction of $A$, it holds $\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right) \geq \sqrt{2 \gamma^{-1} h}+r_{s}(k)$. Then by (28), it holds for all $t \in\left[\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right), \bar{r}_{s}(k)\right]$

$$
\begin{align*}
f^{\prime \prime}(t) & =\left(-f^{\prime}(t) 128 \alpha \gamma^{2} t-\frac{\hat{c} \gamma}{2} \int_{0}^{t} \phi(s) \mathrm{d} s\right) \\
& \leq\left(-\frac{1}{2} \psi\left(r_{s}(k)\right) \phi(t) 128 \alpha \gamma^{2} \sqrt{2 \gamma^{-1} h}-\frac{\hat{c} \gamma}{2} \int_{0}^{r_{s}(k)+\sqrt{2 h \gamma^{-1}}} \phi(s) \mathrm{d} s\right) \\
& \leq\left(-\frac{1}{2} \psi\left(r_{s}(k)\right) \phi\left(r_{s}(k)\right) 128 \alpha \gamma^{2} \frac{\phi\left(\bar{r}_{s}(k)\right)}{\phi\left(r_{s}(k)\right)} \sqrt{2 \gamma^{-1} h}-\frac{\hat{c} \gamma}{2} \int_{0}^{r_{s}(k)+\sqrt{2 h \gamma^{-1}}} \phi(s) \mathrm{d} s\right) . \tag{44}
\end{align*}
$$

Since by (8) it holds $8(6+\alpha h \gamma) \leq 50,(6+\alpha h \gamma)(8+\alpha h \gamma) \leq 50,128 \alpha \gamma^{2}(50 \alpha+50)\left(\gamma^{-1} h\right) \leq 2 / 3$ and $128 \alpha \gamma^{2} h \gamma^{-1}(8 \alpha+4) \leq 2 / 3$, we obtain

$$
\begin{aligned}
\frac{\phi\left(\bar{r}_{s}(k)\right)}{\phi\left(r_{s}(k)\right)} & =\exp \left(-128 \alpha \gamma^{2} \frac{\bar{r}_{s}(k)^{2}-r_{s}(k)^{2}}{2}\right) \\
& \geq \exp \left(-128 \alpha \gamma^{2} \frac{\left(r_{s}(k)+\sqrt{2 \gamma^{-1} h}(6+\alpha h \gamma)\right)^{2}-r_{s}(k)^{2}}{2}\right) \\
& \geq \exp \left(-128 \alpha \gamma^{2} \frac{\left(2(4 \alpha+1) 2 \gamma^{-1} h(6+\alpha h \gamma)+2 \gamma^{-1} h(6+\alpha h \gamma)^{2}\right)}{2}\right) \\
& \geq \exp \left(-128 \alpha \gamma^{2} \frac{\left(2(4 \alpha) 2 \gamma^{-1} h(6+\alpha h \gamma)+2 \gamma^{-1} h(6+\alpha h \gamma)(8+\alpha h \gamma)\right)}{2}\right) \geq \frac{1}{2}
\end{aligned}
$$

and

$$
\begin{align*}
\frac{r_{s}(k)}{\sqrt{2 \gamma^{-1} h}} \int_{0}^{r_{s}(k)+\sqrt{2 h \gamma^{-1}} \phi(s) \mathrm{d} s} & \geq \frac{r_{s}(k)}{\sqrt{2 \gamma^{-1} h}}\left(r_{s}(k)+\sqrt{2 h \gamma^{-1}}\right) \phi\left(r_{s}(k)+\sqrt{2 h \gamma^{-1}}\right) \\
& \geq \int_{0}^{r_{s}(k)} \phi(s) \mathrm{d} s \frac{r_{s}(k)+\sqrt{2 h \gamma^{-1}}}{\sqrt{2 \gamma^{-1} h}} \phi\left(r_{s}(k)+\sqrt{2 h \gamma^{-1}}\right) \\
& \geq \int_{0}^{r_{s}(k)} \phi(s) \mathrm{d} s \phi\left(\sqrt{(4 \alpha+1) 2 \gamma^{-1} h}+\sqrt{2 h \gamma^{-1}}\right) \\
& \geq f\left(r_{s}(k)\right) \exp \left(-128 \alpha \gamma^{2} \frac{1}{2}\left(8 h \gamma^{-1}\right)\right) \geq \frac{1}{2} f\left(r_{s}(k)\right) \tag{45}
\end{align*}
$$

Inserting these two bounds in $f^{\prime \prime}(t)$ and taking the maximum over $t \in\left[\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right), \bar{r}_{s}(k)\right]$ it holds

$$
\max _{t \in\left[\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right), \bar{r}_{s}(k)\right]} f^{\prime \prime}(t) \leq-\frac{1}{4} f^{\prime}\left(r_{s}(k)\right) 128 \alpha \gamma^{2} \sqrt{2 \gamma^{-1} h}-\frac{\hat{c} \gamma}{4} \frac{\sqrt{2 \gamma^{-1} h}}{r_{s}(k)} f\left(r_{s}(k)\right)
$$

which yields

$$
\begin{aligned}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \\
& \quad \leq \frac{(\alpha h \gamma+1)^{2}\left(2 \gamma^{-1} h\right)}{8}\left(-32 \alpha \gamma^{2} f^{\prime}\left(r_{s}(k)\right) \sqrt{2 \gamma^{-1} h}-\frac{\hat{c} \gamma}{4} \frac{\sqrt{2 \gamma^{-1} h}}{(4 \alpha+1)\left|q_{k}\right|} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\mathbb{1}_{A}\right]
\end{aligned}
$$

Note that we used $r_{s}(k) \leq(4 \alpha+1)\left|q_{k}\right|$. For the expectation $\mathbb{E}\left[\mathbb{1}_{A}\right]$ it holds

$$
\begin{aligned}
\mathbb{E}\left[\mathbb{1}_{A}\right] & =\int_{-\left|\hat{q}_{k}\right| / 2}^{\infty} \mathbb{1}_{\left\{2 \sqrt{2 \gamma^{-1} h}+\left|\hat{q}_{k}\right| \leq \sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+2 u\right| \leq\left|\hat{q}_{k}\right|+6 \sqrt{2 \gamma^{-1} h}\right\}}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right) \mathrm{d} u \\
& =\int_{1}^{3} \varphi(u) \mathrm{d} u-\int_{1+\left|q_{k}\right| / \sqrt{2 \gamma^{-1} h}}^{3+\left|q_{k}\right| / \sqrt{2 \gamma^{-1} h}} \varphi(u) \mathrm{d} u=: F\left(\left|q_{k}\right|\right) .
\end{aligned}
$$

By [19, Lemma 3.4] and since $\left|q_{k}\right| \leq \sqrt{2 \gamma^{-1} h}$, this term is bounded from below by

$$
\begin{align*}
\mathbb{E}\left[\mathbb{1}_{A}\right] & \geq \min \left(\frac{F\left(\sqrt{2 \gamma^{-1} h}\right)}{\sqrt{2 \gamma^{-1} h}}, F^{\prime}(0)\right)\left|q_{k}\right| \\
& =\min \left(\int_{1}^{3} \varphi(u) \mathrm{d} u-\int_{1+1}^{3+1} \varphi(u) \mathrm{d} u, \frac{1}{\sqrt{2 \pi}}\left(e^{-\frac{1^{2}}{2}}-e^{-\frac{3^{2}}{2}}\right)\right) \frac{\left|q_{k}\right|}{\sqrt{2 \gamma h^{-1}}} \geq \frac{1}{8} \frac{\left|q_{k}\right|}{\sqrt{2 \gamma h^{-1}}} . \tag{46}
\end{align*}
$$

Hence, we obtain

$$
\begin{aligned}
\mathbb{E} & {\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] } \\
& \leq \frac{1}{8} \frac{(\alpha h \gamma+1)^{2}\left(2 \gamma^{-1} h\right)}{8}\left(-32 \alpha \gamma^{2} f^{\prime}\left(r_{s}(k)\right)\left|q_{k}\right|-\frac{\hat{c} \gamma}{4(4 \alpha+1)} f\left(r_{s}(k)\right)\right) \\
& \leq\left(-\left(\gamma^{-1} h\right) \alpha \gamma^{2} f^{\prime}\left(r_{s}(k)\right)\left|q_{k}\right|-\frac{1}{8}\left(\gamma^{-1} h\right) \frac{\hat{c} \gamma}{16(4 \alpha+1)} f\left(r_{s}(k)\right)\right) .
\end{aligned}
$$

Inserting this bound in (43), we obtain

$$
\begin{aligned}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq f^{\prime}\left(r_{s}(k)\right) \alpha h \gamma\left|q_{k}\right|-\left(\gamma^{-1} h\right) \alpha \gamma^{2} f^{\prime}\left(r_{s}(k)\right)\left|q_{k}\right|-\left(\gamma^{-1} h\right) \frac{\hat{c} \gamma}{128(4 \alpha+1)} f\left(r_{s}(k)\right) \\
& \leq-\left(\gamma^{-1} h\right) \frac{\hat{c} \gamma}{128(4 \alpha+1)} f\left(r_{s}(k)\right)
\end{aligned}
$$

Combining the three cases we obtain for $D_{\mathcal{K}}+\epsilon r_{l}(k)>r_{s}(k)$

$$
\begin{equation*}
\mathbb{E}\left[\rho_{k+1}\right] \leq \mathbb{E}\left[f\left(r_{s}(k+1)\right)\right] \leq\left(1-c_{2} h\right) f\left(r_{s}(k)\right)=\left(1-c_{2} h\right) \rho_{k} \tag{47}
\end{equation*}
$$

with

$$
c_{2}=\min \left(\frac{f^{\prime}\left(R_{1}\right) \gamma}{8}, \frac{f^{\prime}\left(R_{1}\right) \gamma \alpha}{2}, \frac{9}{640} \hat{c}, \frac{\hat{c}}{128(4 \alpha+1)}\right) .
$$

Combining this estimate with the first case $\left(D_{\mathcal{K}}+\epsilon r_{l}(k) \leq r_{s}(k)\right)$, we obtain

$$
\begin{equation*}
\mathbb{E}\left[\rho_{k+1}\right] \leq(1-c h) \rho_{k} \tag{48}
\end{equation*}
$$

with $c$ given in (10).

Proof of Theorem 3. Set $l=\left\lceil\frac{1}{h \gamma \max (\alpha, 1+\alpha / 2)}\right\rceil$. By (11), we have

$$
\begin{aligned}
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) & =\mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{h, \infty} \pi_{h}^{l}\right) \leq \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right)+\mathcal{W}_{\rho}\left(\mu_{\infty} \pi_{h}^{l}, \mu_{h, \infty} \pi_{h}^{l}\right) \\
& \leq \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right)+(1-c h)^{l} \mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) .
\end{aligned}
$$

Hence, by $(1-c h) \leq e^{-c h}, l h \geq \frac{1}{\gamma \max (\alpha, 1+\alpha / 2)}$ and (26),

$$
\begin{aligned}
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) & \leq \frac{1}{1-(1-c h)^{l}} \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right) \leq\left(1-e^{-c h l}\right)^{-1} \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right) \\
& \leq\left(1-e^{\left.-\frac{c}{h \gamma \max (\alpha, 1+\alpha / 2)}\right)^{-1} \mathbb{E}\left[\alpha\left|X_{h l}-\mathbf{X}_{l}\right|+\left|\left(X_{h l}-\mathbf{X}_{l}\right)+\gamma^{-1}\left(V_{h l}-\mathbf{V}_{l}\right)\right|\right]} .\right.
\end{aligned}
$$

with $\left(X_{0}, V_{0}\right)=\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right) \sim \mu_{\infty}$ and where $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)_{k}$ and $\left(X_{s}, V_{s}\right)_{s}$ are synchronously coupled, i.e., $\xi_{k}=\int_{h(k-1)}^{h k} \mathrm{~d} B_{s}$. Define the sequences $\left(a_{k}\right)_{k=0}^{l}$ and $\left(b_{k}\right)_{k=0}^{l}$ by

$$
a_{k}=\mathbb{E}\left[\alpha\left|X_{h k}-\mathbf{X}_{k}\right|\right] \quad \text { and } \quad b_{k}=\mathbb{E}\left[\left|\left(X_{h k}-\mathbf{X}_{k}\right)+\gamma^{-1}\left(V_{h k}-\mathbf{V}_{k}\right)\right|\right] .
$$

By using (1) and (2) iteratively and $a_{0}=b_{0}=0$, it holds

$$
\begin{aligned}
a_{k+1} & \leq \mathbb{E}\left[\alpha\left|X_{k h}-\mathbf{X}_{k}+\int_{0}^{h}\left(V_{h k+s}-\mathbf{V}_{k}\right) \mathrm{d} s\right|\right] \\
& \leq \mathbb{E}\left[\alpha\left|X_{0}-\mathbf{X}_{0}+\sum_{i=0}^{k} \int_{0}^{h}\left(V_{h i+s}-V_{h i}\right) \mathrm{d} s+\sum_{i=0}^{k} h\left(V_{h i}-\mathbf{V}_{i}\right)\right|\right] \\
& \leq \mathbb{E}\left[\alpha\left|\sum_{i=0}^{k} \int_{0}^{h}\left(V_{h i+s}-V_{h i}\right) \mathrm{d} s\right|\right]+\alpha \sum_{i=0}^{k} h \mathbb{E}\left[\left|V_{h i}-\mathbf{V}_{i}\right|\right] \\
& \leq h \mathbf{M}_{2}+h \gamma \sum_{i=1}^{k}\left(\alpha b_{i}+a_{i}\right)
\end{aligned}
$$

where using Lemma 12 and $l h \leq 2 /(\gamma(1+\alpha))$, the constant $\mathbf{M}_{\mathbf{2}}$ is given by

$$
\begin{align*}
h^{-1} \mathbb{E}\left[\alpha\left|\sum_{i=0}^{k} \int_{0}^{h}\left(V_{h i+s}-V_{h i}\right) \mathrm{d} s\right|\right] & \leq \frac{\alpha h}{2} l(\sqrt{L}+\gamma) \sqrt{d}+\alpha \sqrt{2 \gamma d l h} \\
& \leq \frac{\alpha}{\gamma(1+\alpha)}(\sqrt{L}+\gamma) \sqrt{d}+2 \alpha \sqrt{\frac{d}{1+\alpha}}=: \mathbf{M}_{\mathbf{2}} . \tag{49}
\end{align*}
$$

Further,

$$
\begin{aligned}
b_{k+1} & \leq b_{k}+\mathbb{E}\left[\int_{0}^{h} \gamma^{-1}\left|\nabla U\left(X_{h k+s}\right)-\nabla U\left(\mathbf{X}_{k}\right)\right| \mathrm{d} s\right] \leq b_{k}+\mathbb{E}\left[\int_{0}^{h} \gamma^{-1} L\left|X_{h k+s}-\mathbf{X}_{k}\right| \mathrm{d} s\right] \\
& \leq b_{k}+\frac{\alpha \gamma h}{2} a_{k}+\mathbb{E}\left[\int_{0}^{h} \gamma^{-1} L\left|X_{h k+s}-X_{k h}\right| \mathrm{d} s\right] \\
(50) \quad & \leq b_{0}+\sum_{i=0}^{k} \frac{\alpha \gamma h}{2} a_{i}+\sum_{i=0}^{k} \mathbb{E}\left[\int_{0}^{h} \gamma^{-1} L\left|X_{h i+s}-X_{i h}\right| \mathrm{d} s\right] .
\end{aligned}
$$

Then by Lemma 12 and the definition of $l$, we have for all $1 \leq k<l$

$$
\begin{equation*}
\sum_{i=0}^{k} \mathbb{E}\left[\int_{0}^{h}\left|X_{i h+s}-X_{i h}\right| \mathrm{d} s\right] \leq \frac{h^{2}}{2} l \sqrt{d} \leq \frac{h}{\gamma(1+\alpha)} \sqrt{d}=: h \mathbf{M}_{1} \tag{51}
\end{equation*}
$$

Since $a_{0}=0$,

$$
b_{k+1} \leq \sum_{i=1}^{k} \frac{\alpha \gamma h}{2} a_{i}+\gamma^{-1} \operatorname{Lh} \mathbf{M}_{1}
$$

Putting the bound for $a_{k+1}$ and $b_{k+1}$ together, we obtain

$$
\left(a_{k+1}+b_{k+1}\right) \leq h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right)+h \gamma \max (\alpha, 1+\alpha / 2) \sum_{i=1}^{k}\left(a_{i}+b_{i}\right)
$$

We note that the sequence $\left(a_{k}+b_{k}\right)_{k}$ is bounded from above by the sequence $\left(c_{k}\right)_{k}$ (i.e., $a_{k}+b_{k} \leq c_{k}$ for all $k$ ) satisfying

$$
c_{k+1}=h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right)+h \gamma \max (\alpha, 1+\alpha / 2) \sum_{i=1}^{k} c_{i}
$$

and $c_{1}=h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right)$. Set $\lambda=\max (\alpha, 1+\alpha / 2)$. For $\left(c_{k}\right)_{k}$ we observe

$$
\begin{aligned}
a_{k+1}+b_{k+1} & \leq c_{k+1}=h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right)+h \gamma \lambda \sum_{i=1}^{k-1} c_{i}+h \gamma \lambda c_{k} \\
& =(1+h \gamma \lambda) c_{k}=(1+h \gamma \lambda)^{k} c_{1} \leq e^{h \gamma \lambda k} c_{1}=e^{h \gamma \lambda k} h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right)
\end{aligned}
$$

Then, by the choice of $l,(51),(49)$ and $(21)$, it holds

$$
\begin{aligned}
e^{h \gamma \lambda k} h\left(\gamma^{-1} L \mathbf{M}_{1}+\mathbf{M}_{2}\right) & =e^{1} h\left(\gamma^{-1} L \frac{\sqrt{d}}{\gamma(1+\alpha)}+\frac{\alpha}{\gamma(1+\alpha)}(\sqrt{L}+\gamma) \sqrt{d}+2 \alpha \sqrt{\frac{d}{1+\alpha}}\right) \\
& =e^{1} h\left(L \gamma^{-2} \sqrt{d}\right)\left(\frac{3+\sqrt{L \gamma^{-2}}}{1+2 L \gamma^{-2}}+\frac{4}{\sqrt{1+2 L \gamma^{-2}}}\right) \leq 20 h L \gamma^{-2} \sqrt{d}
\end{aligned}
$$

and hence
(52) $\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \leq\left(1-e^{-\frac{c}{\gamma \max (\alpha, 1+\alpha / 2)}}\right)^{-1} 20 h L \gamma^{-2} \sqrt{d} \leq\left(1+\frac{\gamma(1+\alpha)}{c}\right) 20 h L \gamma^{-2} \sqrt{d}$.
where we used in the second step that $1 /\left(1-e^{-x}\right) \leq 1+1 / x$ for $x>0$.

Lemma 12. Consider the kinetic Langevin dynamics with initial distribution $\mu_{\infty}$. Let $l \in \mathbb{N}$. Then, for all $k \in\{0, \ldots, l-1\}$

$$
\begin{aligned}
& \mathbb{E}\left[\int_{0}^{h}\left|X_{k h+s}-X_{k h}\right| \mathrm{d} s\right] \leq \frac{h^{2}}{2} \sqrt{d} \\
& \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h} V_{i h+s}-V_{i h} \mathrm{~d} s\right|\right] \leq \frac{h^{2}}{2} l(\sqrt{L}+\gamma) \sqrt{d}+\sqrt{2 \gamma d l h} h
\end{aligned}
$$

Proof of Lemma 12. By (1), it holds

$$
\begin{equation*}
\int_{0}^{h}\left|X_{k h+s}-X_{k h}\right| \mathrm{d} s=\int_{0}^{h}\left|\int_{0}^{s} V_{k h+r} \mathrm{~d} r\right| \mathrm{d} s \leq \int_{0}^{t} \int_{0}^{s}\left|V_{k h+r}\right| \mathrm{d} r \mathrm{~d} s \tag{53}
\end{equation*}
$$

Taking expectation yields

$$
\mathbb{E}\left[\int_{0}^{h}\left|X_{k h+s}-X_{k h}\right| \mathrm{d} s\right] \leq \mathbb{E}\left[\int_{0}^{t} \int_{0}^{s}\left|V_{k h+r}\right| \mathrm{d} r \mathrm{~d} s\right]=\int_{0}^{t} \int_{0}^{s} \mathbb{E}\left[\left|V_{k h+r}\right|\right] \mathrm{d} r \mathrm{~d} s=\frac{h^{2}}{2} \sqrt{d}
$$

since for $\left(X_{k h+r}, V_{k h+r}\right) \sim \mu_{\infty}$ for all $k \in \mathbb{N}$ and $r \in[0, h]$ and $\left\|V_{k h+r}\right\|_{L^{1}\left(\mu_{\infty}\right)} \leq \sqrt{d}$ by [25, Lemma A.3]. Further by (1)

$$
\begin{align*}
& \left|\sum_{i=0}^{k} \int_{0}^{h} V_{i h+s}-V_{i h} \mathrm{~d} s\right|=\left|\sum_{i=0}^{k} \int_{0}^{h} \int_{0}^{s}-\nabla U\left(X_{i h+r}\right)-\gamma V_{i h+r} \mathrm{~d} r+\sqrt{2 \gamma} \int_{0}^{s} \mathrm{~d} B_{i h+r} \mathrm{~d} s\right| \\
& \quad \leq \sum_{i=0}^{k} \int_{0}^{h} \int_{0}^{s}\left(\left|\nabla U\left(X_{i h+r}\right)\right|+\gamma\left|V_{i h+r}\right|\right) \mathrm{d} r \mathrm{~d} s+\sqrt{2 \gamma}\left|\sum_{i=0}^{k} \int_{0}^{h}\left(B_{i h+s}-B_{i h}\right) \mathrm{d} s\right| . \tag{54}
\end{align*}
$$

We note that $\sum_{i=0}^{k}\left(B_{i h+s}-B_{i h}\right)$ is a normally distributed random variable with mean zero and covariance matrix $((k+1) s) I_{d}$. Further, for $\left(X_{i h+r}, V_{i h+r}\right) \sim \mu_{\infty}$ for all $i \in \mathbb{N},\left\|V_{i h+r}\right\|_{L^{1}\left(\mu_{\infty}\right)} \leq$ $\sqrt{d}$ and $\left\|\nabla U\left(X_{i h+r}\right)\right\|_{L^{1}\left(\mu_{\infty}\right)} \leq \sqrt{L d}$ by [25, Lemma A.3]. Then since $k<l$,

$$
\begin{aligned}
\mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h} V_{i h+s}-V_{i h} \mathrm{~d} s\right|\right] & \leq \mathbb{E}\left[\sum_{i=0}^{k} \int_{0}^{h} \int_{0}^{s}\left(\left|\nabla U\left(X_{i h+r}\right)\right|+\gamma\left|V_{i h+r}\right|\right) \mathrm{d} r \mathrm{~d} s\right. \\
& \left.+\sqrt{2 \gamma}\left|\sum_{i=0}^{k} \int_{0}^{h}\left(B_{i h+s}-B_{i h}\right) \mathrm{d} s\right|\right] \\
& \leq \frac{h^{2}}{2} l(\sqrt{L d}+\gamma \sqrt{d})+\sqrt{2 \gamma d l h} h .
\end{aligned}
$$

Proof of Theorem 4. Applying the triangle inequality and combining Theorem 1 and Theorem 3, it holds for all $k \in \mathbb{N}$

$$
\begin{aligned}
\mathcal{W}_{\rho}\left(\mu_{\infty}, \nu \pi_{h}^{k}\right) & \leq \mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right)+\mathcal{W}_{\rho}\left(\mu_{h, \infty}, \nu \pi_{h}^{k}\right) \\
& \leq h\left(1+\frac{\gamma(1+\alpha)}{c}\right) 20 L \gamma^{-2} \sqrt{d}+e^{-c h k} \mathcal{W}_{\rho}\left(\mu_{h, \infty}, \nu\right)
\end{aligned}
$$

The bound in $\mathcal{W}_{1}$ is obtained by using the equivalence of the distance $\rho$ and the Euclidean distance in $\mathbb{R}^{2 d}$.

## 5.2. $U B U$

Proof of Theorem 6. Since the scheme satisfies $\left(\mathcal{U}_{1 / 2} \mathcal{B} \mathcal{U}_{1 / 2}\right)^{n}=\mathcal{U}_{1 / 2}(\mathcal{B U})^{n-1} \mathcal{B} \mathcal{U}_{1 / 2}$, where $\mathcal{U}_{1 / 2}$ is a half step, we use the contraction result of Theorem 5 for the steps $(\mathcal{B} \mathcal{U})^{n-1}$ and it remains to control the error induced by the steps $\mathcal{U}_{1 / 2}$ and $\mathcal{B} \mathcal{U}_{1 / 2}$. Using a synchronous coupling, we show that there exists a constant $\mathbf{C}$ such that for any $x, v, x^{\prime}, v^{\prime} \in \mathbb{R}^{d}$ and $\xi^{(1)}, \xi^{(2)} \sim \mathcal{N}\left(0, I_{d}\right)$

$$
\begin{aligned}
& \rho\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right) \leq \mathbf{C} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right), \quad \text { and } \\
& \rho\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right) \leq \mathbf{C} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right),
\end{aligned}
$$

where

$$
\begin{array}{ll}
\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right)=\mathcal{U}\left(x, v, \frac{h}{2}, \xi^{(1)}, \xi^{(2)}\right), & \left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right)=\mathcal{B}\left(\mathcal{U}\left(x, v, \frac{h}{2}, \xi^{(1)}, \xi^{(2)}\right), h\right) \\
\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)=\mathcal{U}\left(x^{\prime}, v^{\prime}, \frac{h}{2}, \xi^{(1)}, \xi^{(2)}\right), & \left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)=\mathcal{B}\left(\mathcal{U}\left(x^{\prime}, v^{\prime}, \frac{h}{2}, \xi^{(1)}, \xi^{(2)}\right), h\right) .
\end{array}
$$

We write

$$
\begin{array}{ll}
Z_{U}=\mathbf{X}_{U}-\mathbf{X}_{U}^{\prime}, \quad W_{U}=\mathbf{V}_{U}-\mathbf{V}_{U}^{\prime}, & Z_{B U}=\mathbf{X}_{B U}-\mathbf{X}_{B U}^{\prime}, \quad W_{B U}=\mathbf{V}_{B U}-\mathbf{V}_{B U}^{\prime}, \\
q_{U}=Z_{U}+\gamma^{-1} W_{U}, & q_{B U}=Z_{B U}+\gamma^{-1} W_{B U}
\end{array}
$$

and $z=x-x^{\prime}, w=v-v^{\prime}$ and $q=z+\gamma^{-1} w$.
First, we assume that $x, v, x^{\prime}, v^{\prime} \in \mathbb{R}^{d}$ are such that $\rho\left((x, v),\left(x^{\prime}, v\right)\right)=f\left(r_{s}\left((x, v),\left(x^{\prime}, v\right)\right)\right)$. By the construction of the $\mathcal{U}$ step it holds

$$
\begin{aligned}
\alpha\left|Z_{U}\right|+\left|q_{U}\right| & =\alpha\left|z+\left(1-\exp ^{-\gamma h / 2}\right)(q-z)\right|+|q| \\
& \leq \alpha|z| \exp ^{-\gamma h / 2}+(1+\alpha \gamma h / 2)|q| \leq(1+\alpha \gamma h / 2)(\alpha|z|+|q|)
\end{aligned}
$$

Since $f$ is concave and $(1+\alpha \gamma h / 2) \geq 1$, it holds

$$
\begin{aligned}
\rho\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\right. & \left.\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right) \leq f\left(r_{s}\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right)\right. \\
& \leq f\left((1+\alpha \gamma h / 2) r_{s}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)\right) \leq(1+\alpha \gamma h / 2) \rho\left((x, v),\left(x^{\prime}, v\right)\right) .
\end{aligned}
$$

Analogously, it holds

$$
\begin{aligned}
\alpha\left|Z_{B U}\right|+\left|q_{B U}\right| & =\alpha\left|z+\left(1-e^{-\gamma h / 2}\right)(q-z)\right|+\left|q-h \gamma^{-1} e^{-\gamma h / 2}\left(\nabla U(x)-\nabla U\left(x^{\prime}\right)\right)\right| \\
& \leq \alpha|z| e^{-\gamma h / 2}+h \gamma^{-1} L e^{-\gamma h / 2}|z|+(1+\alpha \gamma h / 2)|q| \\
& \leq \alpha(1+h \gamma / 2) e^{-\gamma h / 2}|z|+(1+\alpha \gamma h / 2)|q| \leq(1+\alpha \gamma h / 2)(\alpha|z|+|q|) .
\end{aligned}
$$

Hence, since $f$ is concave and $(1+\alpha \gamma h / 2) \geq 1$,

$$
\begin{aligned}
\rho\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right) & \leq f\left(r_{s}\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right)\right) \\
& \leq(1+\alpha \gamma h / 2) \rho\left((x, v),\left(x^{\prime}, v\right)\right) .
\end{aligned}
$$

Next, let $x, v, x^{\prime}, v^{\prime} \in \mathbb{R}^{d}$ be such that $\rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)=f\left(D_{\mathcal{K}}+\epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)\right)$ holds. We observe that

$$
r_{l}^{2}\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right)=(z, w)^{T}\left(I_{2 d}+P_{2}\right)^{T} M\left(I_{2 d}+P_{2}\right)(z, w),
$$

with $M$ given in the proof of Proposition 14 and

$$
P_{2}=\left(\begin{array}{cc}
0_{d} & \left(1-e^{\gamma h / 2}\right) \gamma^{-1} I_{d} \\
0_{d} & \left(e^{-\gamma h / 2}-1\right) I_{d}
\end{array}\right)
$$

where $0_{d}$ is the $d \times d$ zero matrix. We want to show that $(z, w)^{T}\left(P_{2}^{T} M+M P_{2}+P_{2} M P_{2}\right)$. $(z, w) \leq C r_{l}^{2}(z, w)$ for some positive constant $C>0$. It holds

$$
P_{2}^{T} M+M P_{2}+P_{2} M P_{2}=\frac{1-e^{-\gamma h / 2}}{\gamma}\left(\begin{array}{cc}
0_{d} & \gamma^{-2} K+\frac{-2 \tau(1-2 \tau)}{2} I_{d} \\
\gamma^{-2} K+\frac{-2 \tau(1-2 \tau)}{2} I_{d} & -\frac{2 \tau+1}{\gamma} e^{-\gamma h / 2} I_{d}
\end{array}\right) .
$$

For $(z, w) \in \mathbb{R}^{2 d}$ it holds

$$
w^{T} \gamma^{-2} K \cdot z+z^{T} \gamma^{-2} K \cdot w \leq \gamma^{-1} z^{T} K \cdot z+\gamma^{-3} w^{T} K \cdot w .
$$

Hence,

$$
\begin{aligned}
& (z, w)^{T}\left(P_{2}^{T} M+M P_{2}+P_{2} M P_{2}\right) \cdot(z, w) \\
& \leq \frac{1-e^{-\gamma h / 2}}{\gamma}\left(\gamma^{-1} z^{T} K \cdot z+\gamma^{-3} w^{T} K \cdot w-2 \tau(1-2 \tau) z \cdot w-\frac{2 \tau+1}{\gamma} e^{-\gamma h / 2}|w|^{2}\right) \\
& \leq \frac{1-e^{-\gamma h / 2}}{\gamma}\left(-2 \tau \gamma(z, w)^{T} M \cdot(z, w)+2 \gamma^{-1} z^{T} K \cdot z+\gamma^{-3} w^{T} K \cdot w\right) \\
& \leq \frac{1-e^{-\gamma h / 2}}{\gamma} 2 \gamma \max \left(1, L_{K} \gamma^{-2}\right)(z, w)^{T} M \cdot(z, w) \leq h \gamma \max \left(1, L_{K} \gamma^{-2}\right)(z, w)^{T} M \cdot(z, w) .
\end{aligned}
$$

Thus,

$$
\begin{aligned}
D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right) & \leq D_{\mathcal{K}}+\sqrt{1+h \gamma \max \left(1, L_{K} \gamma^{-2}\right)} \epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right) \\
& \leq \sqrt{1+h \gamma \max \left(1, L_{K} \gamma^{-2}\right)}\left(D_{\mathcal{K}}+\epsilon r_{l}\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)\right)
\end{aligned}
$$

By concavity of $f$

$$
\rho\left(\left(\mathbf{X}_{U}, \mathbf{V}_{U}\right),\left(\mathbf{X}_{U}^{\prime}, \mathbf{V}_{U}^{\prime}\right)\right) \leq \sqrt{1+h \gamma \max \left(1, L_{K} \gamma^{-2}\right)} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)
$$

Similarly, we observe that

$$
\begin{aligned}
r_{l}^{2}\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right) & =(z, w)^{T}\left(P_{B U_{1 / 2}}\right)^{T} M\left(P_{B U_{1 / 2}}\right)(z, w) \\
& =(z, w)^{T}\left(\left(I_{2 d}+P_{3}\right) P_{B U}\right)^{T} M\left(\left(I_{2 d}+P_{3}\right) P_{B U}\right)(z, w)
\end{aligned}
$$

where $P_{B U}$ corresponds to a $\mathcal{B U}$ step and $P_{B U_{1 / 2}}$ to a $\mathcal{B \mathcal { U } _ { 1 / 2 }}$ and $P_{3}$ is given by

$$
P_{3}=\left(\begin{array}{cc}
0_{d} & \gamma^{-1}(1-\tilde{\eta} / \eta) I_{d} \\
0_{d} & (\tilde{\eta} / \eta-1) I_{d}
\end{array}\right)
$$

with $\eta=e^{-\gamma h}$ and $\tilde{\eta}=e^{-\gamma h / 2}$. We observe that

$$
\begin{aligned}
\left(I_{2 d}+P_{3}\right)^{T} M\left(I_{2 d}+P_{3}\right) & =M+\left(\begin{array}{ccc}
0_{d} & \gamma^{-1}\left(\frac{\tilde{\eta}}{\eta}-1\right)\left(-\gamma^{-2} K+\tau(1-2 \tau) I_{d}\right) \\
0_{d} & \gamma^{-2}\left(\frac{\tilde{\eta}}{\eta}-1\right) \frac{1+2 \tau}{2} I_{d}
\end{array}\right) \\
& +\left(\begin{array}{ccc}
0_{d} & 0_{d} \\
\gamma^{-1}\left(\frac{\tilde{\eta}}{\eta}-1\right)\left(-\gamma^{-2} K+\tau(1-2 \tau) I_{d}\right) & \gamma^{-2}\left(\frac{\tilde{\eta}}{\eta}-1\right) \frac{1+2 \tau}{2} I_{d}
\end{array}\right) \\
& +\left(\begin{array}{cc}
0_{d} & 0_{d} \\
0_{d} & \gamma^{-2}\left(1-\frac{\tilde{\eta}}{\eta}\right)^{2}\left(K \gamma^{-2}+2 \tau^{2} I_{d}\right)
\end{array}\right) \\
& \prec\left(\begin{array}{cc}
\left.1+2 \tau\left(\frac{\tilde{\eta}}{\eta}-1\right)\right) M+\left(\begin{array}{cc}
\left(\frac{\tilde{\eta}}{\eta}-1\right) \gamma^{-2} K & 0_{d}
\end{array} \gamma^{-2}\left(\frac{\tilde{\eta}}{\eta}-1\right)\left(\gamma^{-2} K+I_{d}\right)\right.
\end{array}\right) \\
& +\left(\begin{array}{cc}
0_{d} & 0_{d} \\
0_{d} & \gamma^{-2}\left(1-\frac{\tilde{\eta}}{\eta}\right)^{2}\left(K \gamma^{-2}+2 \tau^{2} I_{d}\right)
\end{array}\right)
\end{aligned}
$$

since

$$
\begin{equation*}
\gamma^{-1}\left(\frac{\tilde{\eta}}{\eta}-1\right) \gamma^{-2} z^{T} K w \leq \gamma^{-2}\left(\frac{\tilde{\eta}}{\eta}-1\right) \frac{1}{2} z^{T} K z+\gamma^{-4}\left(\frac{\tilde{\eta}}{\eta}-1\right) \frac{1}{2} w^{T} K w \tag{55}
\end{equation*}
$$

By (15) and (20), it holds $\left(\frac{\tilde{\eta}}{\eta}-1\right) \leq e^{\gamma h / 2} \frac{\gamma h}{2} \leq \frac{\gamma h}{2} e^{1 / 30}$ and $\tau \leq 1 / 8$ and hence

$$
\begin{aligned}
\left(I_{2 d}+P_{3}\right)^{T} M\left(I_{2 d}+P_{3}\right) & \prec\left(1+2 \tau \frac{\gamma h e^{\frac{1}{30}}}{2}\right) M+\left(\begin{array}{cc}
\frac{h \gamma^{-1}}{2} e^{\frac{1}{30}} K & 0_{d} \\
0_{d} & \frac{h}{2} e^{\frac{1}{30}}\left(1+\frac{e^{\frac{1}{30}}}{30}\right)\left(\gamma^{-3} K+\gamma^{-1} I_{d}\right)
\end{array}\right) \\
& \prec\left(1+h \gamma \max \left(1, L k \gamma^{-2}\right)\right) M .
\end{aligned}
$$

By Proposition 14, it holds

$$
\begin{aligned}
r_{l}^{2}\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right) & \leq\left(1+h \gamma \max \left(1, L_{k} \gamma^{-2}\right)\right)(z, w)^{T}\left(P_{B U}\right)^{T} M P_{B U}(z, w) \\
& \leq\left(1+h \gamma \max \left(1, L_{k} \gamma^{-2}\right)\right)(z, w)^{T} M(z, w)
\end{aligned}
$$

By concavity of $f$, it holds

$$
\rho\left(\left(\mathbf{X}_{B U}, \mathbf{V}_{B U}\right),\left(\mathbf{X}_{B U}^{\prime}, \mathbf{V}_{B U}^{\prime}\right)\right) \leq \sqrt{1+h \gamma \max \left(1, L_{K} \gamma^{-2}\right)} \rho\left((x, v),\left(x^{\prime}, v^{\prime}\right)\right)
$$

These estimates for the $\mathcal{U}_{1 / 2}$-step and the $\mathcal{B} \mathcal{U}_{1 / 2}$-step combined with the contraction result for the $\mathcal{B U}$-scheme concludes the proof since by (17) $\frac{1}{1-c h} \leq \frac{1}{1-e^{-\gamma h} \gamma h / 16} \leq 1+\gamma h / 16$ and hence $\frac{\max \left((1+\alpha \gamma h / 2)^{2}, 1+\gamma h \max \left(1, L_{k} \gamma^{-2}\right)\right)}{1-c h} \leq \mathbf{C}$.

To prove Theorem 9 and Theorem 10, we first introduce an auxiliary result bounding the difference between the continuous kinetic Langevin dynamics and the UBU discretization scheme.
Lemma 13. Assume that $h<\min \left\{\frac{1}{2 \gamma}, \frac{\gamma}{2 L}\right\}$. Consider the kinetic Langevin dynamics and the $U B U$ scheme with synchronously coupled Brownian motion and with initial points $\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right)=$ $\left(X_{0}, V_{0}\right) \sim \mu_{\infty}$. Assume that Assumption 1 and Assumption 2 is satisfied and, then for $k \in \mathbb{N}$ we have that

$$
\begin{aligned}
& \alpha \mathbb{E}\left[\left|\mathbf{X}_{k}-X_{k h}\right|\right]+\mathbb{E}\left[\left|\mathbf{X}_{k}-X_{k h}+\gamma^{-1}\left(\mathbf{V}_{k}-V_{k h}\right)\right|\right] \\
& \leq e^{3 \max \left\{\gamma, \frac{2 L}{\gamma}\right\} h k}\left(\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}\right)
\end{aligned}
$$

where

$$
\mathbf{M}_{a}=\frac{h^{3}}{24}\left(\left(\frac{\sqrt{42}}{2}+1\right) L+\gamma L^{1 / 2}\right) d^{1 / 2}, \quad \mathbf{M}_{b}=\frac{\gamma^{-1}(k+1) L h^{2} \sqrt{d}}{4}
$$

and if Assumption 2 is satisfied $\mathbf{M}_{b}$ is refined to

$$
\mathbf{M}_{b}=\gamma^{-1}(k+1) \frac{h^{3} \sqrt{d}}{24}\left(L_{1} \sqrt{d}+L^{3 / 2}+\gamma L\right)+\sqrt{2 \gamma^{-1}} \sqrt{\frac{(k+1) h^{5} L^{2} d}{192}}
$$

further if Assumption 3 is satisfied this $\mathbf{M}_{b}$ is refined to

$$
\mathbf{M}_{b}=\gamma^{-1}(k+1) \frac{h^{3} \sqrt{d}}{24}\left(L_{1}^{s}+L^{3 / 2}+\gamma L\right)+\sqrt{2 \gamma^{-1}} \sqrt{\frac{(k+1) h^{5} L^{2} d}{192}}
$$

Proof. [58] use a different formulation of the solution of kinetic Langevin dynamics, which is derived by using Itô's formula on the product $e^{\gamma t} V_{t}$. For initial condition $\left(X_{0}, V_{0}\right) \in \mathbb{R}^{2 d}$ the solution of (1) can be written as:

$$
\begin{align*}
V_{t} & =\mathcal{E}(t) V_{0}-\int_{0}^{t} \mathcal{E}(t-s) \nabla U\left(X_{s}\right) d s+\sqrt{2 \gamma} \int_{0}^{t} \mathcal{E}(t-s) d B_{s}  \tag{56}\\
X_{t} & =X_{0}+\mathcal{F}(t) V_{0}-\int_{0}^{t} \mathcal{F}(t-s) \nabla U\left(X_{s}\right) d s+\sqrt{2 \gamma} \int_{0}^{t} \mathcal{F}(t-s) d B_{s} \tag{57}
\end{align*}
$$

where

$$
\begin{equation*}
\mathcal{E}(t)=e^{-\gamma t} \quad \mathcal{F}(t)=\frac{1-e^{-\gamma t}}{\gamma} \tag{58}
\end{equation*}
$$

Further the UBU scheme (as in [58]) can be expressed as

$$
\begin{align*}
\mathbf{V}_{k+1} & =\mathcal{E}(h) \mathbf{V}_{k}-h \mathcal{E}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{k}\right)+\sqrt{2 \gamma} \int_{k h}^{(k+1) h} \mathcal{E}((k+1) h-s) d B_{s}  \tag{59}\\
\overline{\mathbf{X}}_{k} & =\mathbf{X}_{k}+\mathcal{F}(h / 2) \mathbf{V}_{k}+\sqrt{2 \gamma} \int_{k h}^{(k+1 / 2) h} \mathcal{F}((k+1 / 2) h-s) d B_{s}  \tag{60}\\
\mathbf{X}_{k+1} & =\mathbf{X}_{k}+\mathcal{F}(h) \mathbf{V}_{k}-h \mathcal{F}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{k}\right)+\sqrt{2 \gamma} \int_{k h}^{(k+1) h} \mathcal{F}((k+1) h-s) d B_{s} \tag{61}
\end{align*}
$$

this is convenient for comparison with (56) and (57).
If we consider synchronously coupled Brownian motion with $\left(X_{0}, V_{0}\right)=\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right) \sim \mu_{\infty}$, let us define

$$
a_{k}:=\alpha \mathbb{E}\left[\left|\mathbf{X}_{k}-X_{k h}\right|\right], \quad b_{k}:=\mathbb{E}\left[\left|\mathbf{X}_{k}-X_{k h}+\gamma^{-1}\left(\mathbf{V}_{k}-V_{k h}\right)\right|\right]
$$

then we firstly have

$$
\begin{aligned}
& a_{k+1} \\
& \leq \alpha \mathbb{E}\left[\left|\mathbf{X}_{k}-X_{k h}+\mathcal{F}(h)\left(\mathbf{V}_{k}-V_{k h}\right)-h \mathcal{F}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{k}\right)+\int_{0}^{h} \mathcal{F}(h-s) \nabla U\left(X_{k h+s}\right) d s\right|\right] \\
& \leq \mathbb{E}\left[\alpha\left|\mathbf{X}_{k}-X_{k h}\right|+h \alpha\left|\mathbf{V}_{k}-V_{k h}\right|+\alpha\left|h \mathcal{F}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{k}\right)-\int_{0}^{h} \mathcal{F}(h-s) \nabla U\left(X_{k h+s}\right) d s\right|\right] \\
& \leq a_{0}+\sum_{i=1}^{k} h \gamma\left(\alpha b_{i}+a_{i}\right)+\alpha \sum_{i=0}^{k} \mathbb{E}\left[\left|h \mathcal{F}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{i}\right)-\int_{0}^{h} \mathcal{F}(h-s) \nabla U\left(X_{i h+s}\right) d s\right|\right]
\end{aligned}
$$

where following Section 7.6 of [58] we expand $\mathcal{F}(h-s) \nabla U\left(X_{k h+s}\right)$ by the fundamental theorem of calculus and get

$$
\begin{aligned}
& h \mathcal{F}(h / 2) \nabla U\left(\overline{\mathbf{X}}_{i}\right)-\int_{0}^{h} \mathcal{F}(h-s) \nabla U\left(X_{i h+s}\right) d s \\
& =-h \mathcal{F}(h / 2)\left(\nabla U\left(X_{i h+1 / 2}\right)-\nabla U\left(\overline{\mathbf{X}}_{i}\right)\right)+I_{6}+I_{7}
\end{aligned}
$$

where $I_{6}$ and $I_{7}$ are defined as in [58]

$$
\begin{aligned}
I_{6} & =-\int_{i h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \mathcal{F}\left((i+1) h-s^{\prime}\right) \nabla^{2} U\left(X_{s^{\prime}}\right) V_{s^{\prime}} d s^{\prime} d s \\
I_{7} & =-\int_{i h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \mathcal{E}\left((i+1) h-s^{\prime}\right) \nabla U\left(X_{s^{\prime}}\right) d s^{\prime} d s
\end{aligned}
$$

and they show the following bounds

$$
\mathbb{E}\left|I_{6}+I_{7}\right| \leq\left(\mathbb{E}\left|I_{6}\right|^{2}\right)^{1 / 2}+\left(\mathbb{E}\left|I_{7}\right|^{2}\right)^{1 / 2} \leq \frac{h^{3}}{24}\left(\left(\frac{\sqrt{42}}{2}+1\right) L+\gamma L^{1 / 2}\right) d^{1 / 2}:=\mathbf{M}_{a}
$$

We can also bound

$$
\mathbb{E}\left[\left|-h \mathcal{F}(h / 2)\left(\nabla U\left(X_{(i+1 / 2) h}\right)-\nabla U\left(\overline{\mathbf{X}}_{i}\right)\right)\right|\right] \leq \frac{h^{2}}{2} L \mathbb{E}\left(\left|X_{i h}-\mathbf{X}_{i}\right|+\frac{h}{2}\left|V_{i h}-\mathbf{V}_{i}\right|\right)
$$

and combining these results and using that $h<\min \left\{\frac{1}{2 \gamma}, \frac{\gamma}{2 L}\right\}$, we have

$$
a_{k+1} \leq 2 h \gamma \sum_{i=1}^{k}\left(\alpha b_{i}+a_{i}\right)+\alpha(k+1) \mathbf{M}_{a}
$$

If we consider $b_{k}$ we have

$$
\begin{aligned}
& b_{k+1} \leq b_{0}+\gamma^{-1} \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h}\left(\nabla U\left(X_{i h+s}\right)-\nabla U\left(\overline{\mathbf{X}}_{i}\right)\right) d s\right|\right] \\
& \leq b_{0}+\gamma^{-1} \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h}\left(\nabla U\left(X_{i h+s}\right)-\nabla U\left(X_{(i+1 / 2) h}\right)\right) d s\right|\right] \\
& +h \gamma^{-1} \sum_{i=0}^{k} \mathbb{E}\left[\left|\nabla U\left(\overline{\mathbf{X}}_{i}\right)-\nabla U\left(X_{(i+1 / 2) h}\right)\right|\right]
\end{aligned}
$$

where we now want to bound the second term as we have an estimate for the third term by the previous arguments. Using Îto-Taylor expansion twice as in [58] we have that

$$
\int_{i h}^{(i+1) h} \nabla U\left(X_{s}\right) d s=h \nabla U\left(X_{(i+1 / 2) h}\right)+\int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} d\left(\nabla^{2} U\left(X_{s^{\prime \prime}}\right) v\right) d s^{\prime} d s
$$

where we can use Ito's formula on $\nabla^{2} U\left(X_{s^{\prime \prime}}\right) v$ to get that

$$
\int_{i h}^{(i+1) h}\left(\nabla U\left(X_{s}\right)-\nabla U\left(X_{(i+1 / 2) h}\right)\right) d s=I_{1}+I_{2}+I_{3}+I_{4},
$$

where

$$
\begin{aligned}
& I_{1}=\int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{3} U\left(X_{s^{\prime \prime}}\right)\left[V_{s^{\prime \prime}}, V_{s^{\prime \prime}}\right] d s^{\prime \prime} d s^{\prime} d s \\
& I_{2}=-\gamma \int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) V_{s^{\prime \prime}} d s^{\prime \prime} d s^{\prime} d s \\
& I_{3}=-\int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) \nabla U\left(X_{s^{\prime \prime}}\right) d s^{\prime \prime} d s^{\prime} d s \\
& I_{4}=\sqrt{2 \gamma} \int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) d B_{s^{\prime \prime}} d s^{\prime} d s .
\end{aligned}
$$

We first bound $I_{1}, I_{2}$ and $I_{3}$ as follows. For $I_{1}$ we use the fact that each scalar component of $V_{s^{\prime \prime}} \sim \mathcal{N}\left(0, I_{d}\right)$ and therefore under Assumption 3 and [56, Lemma 7]

$$
\mathbb{E}\left[\left\|\nabla^{3} U\left(X_{s^{\prime \prime}}\right)\left[V_{s^{\prime \prime}}, V_{s^{\prime \prime}}\right]\right\|\right] \leq L_{1}^{s} \sqrt{d}
$$

and therefore

$$
\mathbb{E}\left[\left|I_{1}\right|\right] \leq \frac{L_{1}^{s} \sqrt{d} h^{3}}{24}
$$

Under Assumption 2 similarly we have

$$
\mathbb{E}\left[\left|I_{1}\right|\right] \leq \frac{L_{1} d h^{3}}{24}
$$

To bound $I_{2}$ and $I_{3}$, we observe

$$
\begin{aligned}
\mathbb{E}\left[\left\|\nabla^{2} U\left(X_{s^{\prime \prime}}\right) V_{s^{\prime \prime}}\right\|\right] & \leq L \mathbb{E}\left(\left\|V_{s^{\prime \prime}}\right\|\right) \leq L \sqrt{d} \\
\mathbb{E}\left[\left\|\nabla^{2} U\left(X_{s^{\prime \prime}}\right) \nabla U\left(X_{s^{\prime \prime}}\right)\right\|\right] & \leq L \mathbb{E}\left(\left\|\nabla U\left(X_{s^{\prime \prime}}\right)\right\|\right) \leq L^{3 / 2} \sqrt{d}
\end{aligned}
$$

and therefore

$$
\mathbb{E}\left[\left|I_{2}\right|\right] \leq \frac{\gamma L \sqrt{d} h^{3}}{24}, \mathbb{E}\left[\left|I_{3}\right|\right] \leq \frac{L^{3 / 2} \sqrt{d} h^{3}}{24}
$$

Then we have that

$$
\begin{aligned}
& \gamma^{-1} \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h}\left(\nabla U\left(X_{i h+s}\right)-\nabla U\left(X_{(i+1 / 2) h}\right)\right) d s\right|\right] \\
& \leq \gamma^{-1}(k+1) \frac{h^{3} \sqrt{d}}{24}\left(L_{1}+L^{3 / 2}+\gamma L\right) \\
& +\sqrt{2 \gamma^{-1}} \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) d B_{s^{\prime \prime}} d s^{\prime} d s\right|\right] .
\end{aligned}
$$

We can estimate the final expectation by considering Jensen's inequality and considering the estimate of the second moment

$$
\mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) d B_{s^{\prime \prime}} d s^{\prime} d s\right|^{2}\right]
$$

using the fact that the Brownian motions are over disjoint time intervals corresponding to each $0 \leq i \leq k$ we can apply Fubini's theorem and Îto's isometry to get

$$
=\sum_{i=0}^{k} \mathbb{E}\left[\left|\int_{(i+1 / 2) h}^{(i+1) h} \int_{(i+1 / 2) h}^{s} \int_{2(i+1 / 2) h-s^{\prime}}^{s^{\prime}} \nabla^{2} U\left(X_{s^{\prime \prime}}\right) d B_{s^{\prime \prime}} d s^{\prime} d s\right|^{2}\right] \leq \frac{(k+1) h^{5} L^{2} d}{192} .
$$

We define $\mathbf{M}_{b}:=\gamma^{-1}(k+1) \frac{h^{3} \sqrt{d}}{24}\left(\mathbf{M}_{c}+L^{3 / 2}+\gamma L\right)+\sqrt{2 \gamma^{-1}} \sqrt{\frac{(k+1) h^{5} L^{2} d}{192}}$ with $\mathbf{M}_{c}=L_{1}^{s}$ under Assumption 3 and $\mathbf{M}_{c}=L_{1} \sqrt{d}$ under Assumption 2.

Further when Assumption 2 and Assumption 3 are not satisfied we use the fundamental theorem of calculus to have that $\nabla U\left(X_{i h+s}\right)=\nabla U\left(X_{(i+1 / 2) h}\right)+\int_{(i+1 / 2) h}^{i h+s} \nabla^{2} U\left(X_{s^{\prime}}\right) V_{s^{\prime}} d s^{\prime}$ and therefore we estimate

$$
\begin{aligned}
& \gamma^{-1} \mathbb{E}\left[\left|\sum_{i=0}^{k} \int_{0}^{h}\left(\nabla U\left(X_{i h+s}\right)-\nabla U\left(\overline{\mathbf{X}}_{i}\right)\right) d s\right|\right] \\
& \leq h \gamma^{-1} \sum_{i=0}^{k} \mathbb{E}\left[\left|\nabla U\left(X_{(i+1 / 2) h}\right)-\nabla U\left(\overline{\mathbf{X}}_{i}\right)\right|\right]+\frac{\gamma^{-1}(k+1) L h^{2} \sqrt{d}}{4} .
\end{aligned}
$$

In this case, we define $\mathbf{M}_{b}:=\frac{\gamma^{-1}(k+1) L h^{2} \sqrt{d}}{4}$.
Combining the estimates we have

$$
b_{k+1} \leq h \sum_{i=1}^{k}\left(\gamma a_{i}+\frac{h L}{2} b_{i}\right)+\mathbf{M}_{b},
$$

and combining this with the iteration inequality for $a_{k+1}$ we obtain

$$
\begin{aligned}
a_{k+1}+b_{k+1} & \leq h \sum_{i=1}^{k}\left(3 \gamma a_{i}+\frac{6 L}{\gamma} b_{i}\right)+\left(\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}\right) \\
& \leq 3 h \max \left\{\gamma, \frac{2 L}{\gamma}\right\} \sum_{i=1}^{k}\left(a_{i}+b_{i}\right)+\left(\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}\right) .
\end{aligned}
$$

Now we note that the sequence $\left(a_{k}+b_{k}\right)_{k \in \mathbb{N}}$ is bounded from above by the sequence $\left(c_{k}\right)_{k \in \mathbb{N}}$ satisfying

$$
c_{k+1}:=3 h \max \left\{\gamma, \frac{2 L}{\gamma}\right\} \sum_{i=1}^{k} c_{i}+\left(\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}\right)
$$

and $c_{1}=\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}$. Then, we have

$$
\begin{aligned}
a_{k+1}+b_{k+1} & \leq c_{k+1}=\left(1+3 h \max \left\{\gamma, \frac{2 L}{\gamma}\right\}\right) c_{k} \\
& \leq\left(1+3 h \max \left\{\gamma, \frac{2 L}{\gamma}\right\}\right)^{k} c_{1} \leq e^{3 \max \left\{\gamma, \frac{2 L}{\gamma}\right\} h k}\left(\mathbf{M}_{b}+\alpha(k+1) \mathbf{M}_{a}\right) .
\end{aligned}
$$

Proof of Theorem 9. Inspired by the interpolation argument used in [43] we define $\left(\mathbf{X}_{l}, \mathbf{V}_{l}\right)$ as $l$ steps of the UBU scheme and $\left(X_{l h}, V_{l h}\right)$ is defined by (1) at time $l h \geq 0$, where these are both initialized at $\left(X_{0}, V_{0}\right)=\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right) \sim \mu_{\infty}$ and have synchronously coupled Brownian motion. We further define a sequence of interpolating variants $\left(\mathbf{X}_{l}^{(k)}, \mathbf{V}_{l}^{(k)}\right)$ for every $k=0, \ldots, l$ all initialized $\left(\mathbf{X}_{0}^{(k)}, \mathbf{V}_{0}^{(k)}\right)=\left(\mathbf{X}_{0}, \mathbf{V}_{0}\right)$, where we define $\left(\mathbf{X}_{l}^{(k)}, \mathbf{V}_{i}^{(k)}\right)_{i=1}^{k}:=\left(X_{i h}, V_{i h}\right)_{i=1}^{k}$ and $\left(\mathbf{X}_{l}^{(k)}, \mathbf{V}_{i}^{(k)}\right)_{i=k+1}^{l}$ by UBU steps and for $k=l$ we simply have just the continuous diffusion (1). Using Lemma 13 we split up the steps into blocks of size $\tilde{l}=\left\lceil\frac{1}{3 h \max \left\{\gamma, \frac{2 L}{\gamma}\right\}}\right\rceil$ as

$$
\begin{aligned}
& \left.\mathcal{W}_{\rho} \mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right) \\
& \quad \leq \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{[l / \tilde{l} \tilde{l} \tilde{l}} \pi_{h}^{l-\lfloor l / \tilde{l} \tilde{l}}, \mu_{\infty} \pi^{l}\right)+\sum_{j=0}^{\lfloor l / \tilde{l}\rfloor-1} \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{j \tilde{l}} \pi_{h}^{l-j \tilde{l}}, \mu_{\infty} \pi^{(j+1) \tilde{l}} \pi_{h}^{l-(j+1) \tilde{l}}\right) .
\end{aligned}
$$

Using the fact that (1) preserves $\mu_{\infty}$ and the remaining steps follow the UBU scheme for which we have contraction we can use Lemma 13 and Theorem 6 to achieve

$$
\mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{j \tilde{l}} \pi_{h}^{l-j \tilde{l}}, \mu_{\infty} \pi^{(j+1) \tilde{l}} \pi_{h}^{l-(j+1) \tilde{l}}\right) \leq \mathbf{C} e^{3 \max \left\{\gamma, \frac{2 L}{\gamma}\right\} h \tilde{l}}\left(\mathbf{M}_{b}+\alpha(\tilde{l}+1) \mathbf{M}_{a}\right)(1-c h)^{l-(j+1) \tilde{l}},
$$

where $\mathbf{M}_{b}$ depends on $\tilde{l}$ and $\mathbf{C}$ is defined as in (19). Summing up the terms we have that

$$
\mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right) \leq \frac{16 \mathbf{C}\left(\mathbf{M}_{b}+\alpha(\tilde{l}+1) \mathbf{M}_{a}\right)}{1-(1-c h)^{\tilde{l}}}
$$

and taking the limit as $l \rightarrow \infty$ in the following estimate we have

$$
\begin{aligned}
\mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) & =\mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{h, \infty} \pi_{h}^{l}\right) \leq \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right)+\mathcal{W}_{\rho}\left(\mu_{\infty} \pi_{h}^{l}, \mu_{h, \infty} \pi_{h}^{l}\right) \\
& \leq \mathcal{W}_{\rho}\left(\mu_{\infty} \pi^{l}, \mu_{\infty} \pi_{h}^{l}\right)+\mathbf{C}(1-c h)^{l} \mathcal{W}_{\rho}\left(\mu_{\infty}, \mu_{h, \infty}\right) \\
& \leq \frac{15 \mathbf{C}\left(\mathbf{M}_{b}+\alpha(\tilde{l}+1) \mathbf{M}_{a}\right)}{1-(1-c h)^{\tilde{l}}} \leq 15 \mathbf{C}\left(\mathbf{M}_{b}+\alpha(\tilde{l}+1) \mathbf{M}_{a}\right)\left(1+\frac{1}{c h \tilde{l}}\right) \\
& \leq 15 \mathbf{C}\left(\mathbf{M}_{b}+\alpha(\tilde{l}+1) \mathbf{M}_{a}\right)\left(1+\frac{3 \max \left\{\gamma, \frac{2 L}{\gamma}\right\}}{c}\right),
\end{aligned}
$$

where we have used that $1 /\left(1-e^{-x}\right) \leq 1+1 / x$ for all $x>0$ and the result follows, where we simplify the estimate.

Proof of Theorem 10. The results follows by applying triangle inequality, Theorem 9, Theorem 6 and using (29).

## Proof of Theorem 5

To show Theorem 5, we first prove a local contraction result for the distance $r_{l}$.
Proposition 14. Let the potential $U$ be of the form $U:=x^{T} K x+G(x)$, where the symmetric and positive definite matrix $K$ satisfies $\kappa I_{d} \prec K \prec L_{K} I_{d}$ and $\nabla G$ is convex for all $x, y \in \mathbb{R}^{d}$ such that $|x-y|>R$, now consider two iterates of the BU scheme $\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right)_{k \in \mathbb{N}}$ and $\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)_{k \in \mathbb{N}}$ with synchronously coupled noise increments and metric $r_{l}$ between the iterates. If $r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \geq \mathcal{R}$ at iteration $k \in \mathbb{N}, h<\min \left\{\frac{\gamma}{55 L_{K}}, \frac{1}{15 \gamma}\right\}$ and $L_{G} \gamma^{-2} \leq$ $\kappa /\left(13 L_{G}\right)$ we have that

$$
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) \leq\left(1-\frac{7}{8} \tau \gamma h\right) r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)
$$

where $\tau=\min \left\{\frac{\kappa}{6 \gamma^{2}}, \frac{1}{16}\right\}$. If $R=0, \mathcal{R}=0$ and the restriction on $\gamma$ improves to $L_{G} \gamma^{-2} \leq \frac{1}{6}$. Proof. We have that

$$
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right)=\left(Z_{k}, W_{k}\right) P^{T} M P \cdot\left(Z_{k}, W_{k}\right),
$$

where
$M=\left(\begin{array}{cc}\gamma^{-2} K+(1-2 \tau)^{2} / 2 I_{d} & (1-2 \tau) / 2 \gamma I_{d} \\ (1-2 \tau) / 2 \gamma I_{d} & \gamma^{-2} I_{d}\end{array}\right)$, and $P=\left(\begin{array}{cc}I_{d}-\frac{1-\eta}{\gamma} h(K+Q) & \left(\frac{1-\eta}{\gamma}\right) I_{d} \\ -h \eta(K+Q) & \eta I_{d}\end{array}\right)$,
where $\eta=\exp (-\gamma h), K$ is the matrix defined by the quadratic term in the potential and $Q$ is defined by

$$
Q=\int_{t=0}^{1} \nabla^{2} G\left(\mathbf{X}_{k}+t\left(\mathbf{X}_{k}^{\prime}-\mathbf{X}_{k}\right)\right) d t
$$

where $G$ is the non-quadratic term in the potential and $Q \succ 0$ for $\left|\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}\right|>R$ and $-L_{G} I_{d} \prec Q \prec L_{G} I_{d}$ otherwise. It holds

$$
\begin{aligned}
r_{l}^{2}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) & =r_{l}^{2}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \\
& +\left(Z_{k}, W_{k}\right)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1}\right)\left(Z_{k}, W_{k}\right)
\end{aligned}
$$

with

$$
P_{1}=\left(\begin{array}{cc}
-\frac{1-\eta}{\gamma}(K+Q) & \frac{1-\eta}{\gamma} I_{d}  \tag{62}\\
-\eta(K+Q) & -\frac{1-\eta}{h} I_{d}
\end{array}\right) .
$$

It is sufficient to show that for all $(z, w) \in \mathbb{R}^{2 d}$ with $r_{l}^{2}((z, w)) \geq \mathcal{R},(z, w)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+\right.$ $\left.h^{2} P_{1}^{T} M P_{1}\right)(z, w) \leq-\gamma \tau h(z, w)^{T} M(z, w)$. It holds

$$
\begin{aligned}
& h\left(M P_{1}+P_{1}^{T} M\right)=h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q) & -\gamma^{-2} Q-\tau(1-2 \tau) I_{d} \\
-\gamma^{-2} Q-\tau(1-2 \tau) I_{d} & -\frac{1+2 \tau}{\gamma} I_{d}
\end{array}\right)+\left(\begin{array}{ll}
A_{h^{2}} & B_{h^{2}} \\
B_{h^{2}} & C_{h^{2}}
\end{array}\right) \\
& \prec h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q)+2 \gamma^{-3} Q^{2} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & \left(-2 \tau \gamma^{-1}-\frac{\gamma^{-1}}{2}\right) I_{d}
\end{array}\right)+\left(\begin{array}{ll}
A_{h^{2}} & B_{h^{2}} \\
B_{h^{2}} & C_{h^{2}}
\end{array}\right),
\end{aligned}
$$

since for all $(z, w) \in \mathbb{R}^{2 d}, z^{T}\left(-Q \gamma^{-2}\right) w \leq \gamma^{-3} z^{T} Q^{2} z+1 / 4 \gamma^{-1}|w|^{2}$ and $w^{T}\left(-Q \gamma^{-2}\right) z \leq$ $\gamma^{-3} z^{T} Q^{2} z+1 / 4 \gamma^{-1}|w|^{2}$ and where
$A_{h^{2}}=h(1-\eta) \frac{1-2 \tau}{\gamma}(K+Q)-h \frac{1-\eta}{\gamma}\left(\gamma^{-2} K+\frac{(1-2 \tau)^{2}}{2} I_{d}\right)(K+Q)$
$-h \frac{1-\eta}{\gamma}(K+Q)\left(\gamma^{-2} K+\frac{(1-2 \tau)^{2}}{2} I_{d}\right)$
$B_{h^{2}}=\frac{(1-\eta-\eta \gamma h)}{\gamma^{3}} K+h(1-\eta) Q / \gamma^{2}+\tau(1-2 \tau) \frac{\gamma h-1+\eta}{\gamma} I_{d}-h \frac{(1-\eta)(1-2 \tau)}{2 \gamma^{2}}(K+Q)$
$C_{h^{2}}=\frac{(h \gamma-1+\eta)(1+2 \tau)}{\gamma^{2}} I_{d}$
and using that $|h \gamma-1+\eta| \leq \frac{h^{2} \gamma^{2}}{2},|h \gamma \eta-1+\eta| \leq|h \gamma-1+\eta|+h \gamma(1-\eta) \leq \frac{3 h^{2} \gamma^{2}}{2}$ for $h<\frac{1}{2 \gamma}$, $w^{T} Q z \leq \frac{1}{2} \gamma^{-1} z^{T} Q^{2} z+\frac{1}{2} \gamma|w|^{2}$ and $w^{T} K z \leq \frac{1}{2} \gamma^{-1} z^{T} K^{2} z+\frac{1}{2} \gamma|w|^{2}$ we have

$$
\begin{aligned}
& \left(\begin{array}{ll}
A_{h^{2}} & B_{h^{2}} \\
B_{h^{2}} & C_{h^{2}}
\end{array}\right) \prec\left(\begin{array}{ll}
1 & 0 \\
0 & 0
\end{array}\right) \otimes\left(A_{h^{2}}+\frac{3 h^{2} Q^{2}}{2 \gamma^{2}}+2 \frac{h^{2} K^{2}}{\gamma^{2}}+\frac{h^{2} \tau(1-2 \tau) \gamma^{2}}{2} I_{d}\right) \\
& +\left(\begin{array}{ll}
0 & 0 \\
0 & 1
\end{array}\right) \otimes\left(\frac{h^{2}(1+2 \tau)}{2} I_{d}+h^{2}\left(\frac{7}{2}+\tau(1-2 \tau) / 2\right) I_{d}\right)
\end{aligned}
$$

We have that $z^{T}(K+Q) w \leq \frac{1}{2 \gamma} z^{T}(K+Q)^{2} z+\frac{\gamma}{2}|w|^{2},(K+Q)^{T} K(K+Q) \prec L_{K}(K+Q)^{2}$ as $K$ is symmetric and positive definite and hence we can take the square root of $K$. Using these identities and also using the aforementioned inequalities for $h$ and $\gamma$ and $h<\frac{1}{12 \gamma}$ we have

$$
\begin{aligned}
& h^{2} P_{1}^{T} M P_{1}= \\
& \left(\begin{array}{cc}
\frac{h^{2}(K+Q)\left(2(1-\eta)^{2} K+\gamma^{2}\left((1-2 \tau)^{2}+4 \eta \tau(1-2 \tau)+\eta^{2}\left(1+4 \tau^{2}\right)\right)\right)(K+Q)}{2 \gamma^{4}} & \frac{-h(1-\eta)(K+Q)\left((1-\eta) K+\gamma^{2}\left(\tau(2 \tau-1)-\eta / 2-2 \eta \tau^{2}\right) I_{d}\right)}{\gamma^{4}} \\
\frac{-h(1-\eta)\left((1-\eta) K+\gamma^{2}\left(\tau(2 \tau-1)-\eta / 2-2 \eta \tau^{2}\right) I_{d}\right)(K+Q)}{\gamma^{4}} & \frac{(1-\eta)^{2}\left(2 K+\gamma^{2}\left(1+4 \tau^{2}\right) I_{d}\right)}{2 \gamma^{4}}
\end{array}\right) \\
& \prec h^{2}\left(\begin{array}{cc}
\frac{5}{2}(K+Q)^{2} \gamma^{-2} & 0 \\
0 & K \gamma^{-2}+\frac{5}{2} I_{d}
\end{array}\right)
\end{aligned}
$$

assuming that $\tau \leq 1 / 16$. Using the fact that $(K+Q)^{2} \prec 2 K^{2}+2 Q^{2} \prec 2 L_{K} K+2 Q^{2}$ and $K Q, Q K \prec L_{K} K+Q^{2}$. Combining the previous estimates we obtain

$$
\begin{aligned}
& h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1} \prec h\left(\begin{array}{cc}
\frac{1-2 \tau}{\gamma}(-K-Q)+2 \gamma^{-3} Q^{2} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & \left(-2 \tau \gamma^{-1}-\frac{\gamma^{-1}}{2}\right) I_{d}
\end{array}\right) \\
& +h^{2}\left(\begin{array}{cc}
(1-2 \tau)\left(2 \tau \frac{1-\eta}{\gamma h}(K+Q)+\frac{\tau \gamma^{2}}{2} I_{d}\right)+9\left(Q^{2}+L_{K} K\right) \gamma^{-2} & 0 \\
0 & K \gamma^{-2}+7 I_{d}
\end{array}\right)
\end{aligned}
$$

We define $C_{\eta, \tau}:=1-2 \tau(1-\eta)$, where $\frac{7}{8} \leq C_{\eta, \tau} \leq 1$ By the conditions on $h$ it holds that $h^{2} \frac{9 L_{K}}{\gamma^{2}} K \prec h \frac{C_{\eta, \tau}(1-4 \tau)}{4 \gamma} K, h\left(L_{k} \gamma^{-2}+7\right) \leq \frac{1}{2 \gamma}$ and $9 h L_{G}^{2} \gamma^{-2} \leq 2 \gamma^{-3} L_{G}^{2}$

$$
\prec h\left(\begin{array}{cc}
\frac{C_{\eta, \tau}(1-2 \tau)}{\gamma}(-K-Q)+\frac{C_{\eta, \tau}(1-4 \tau)}{4 \gamma} K+4 \gamma^{-3} L_{G}^{2} I_{d}+h \tau \gamma^{2}(1-2 \tau) / 2 I_{d} & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & -2 \tau \gamma^{-1} I_{d}
\end{array}\right) .
$$

By assumption on $G$ and $\gamma$ and the choice of $\tau$, we observe

$$
\frac{C_{\eta, \tau}(1-2 \tau)}{\gamma} z^{T}(-Q) z \leq \frac{C_{\eta, \tau}(1-2 \tau)}{\gamma} L_{G} \mathbb{1}_{|z| \leq R}|z|^{2} \leq C_{\eta, \tau} L_{G} \gamma^{-1} R^{2}
$$

and due to the condition on $\gamma$ and $\tau<\kappa / 6 \gamma^{2}$

$$
\begin{aligned}
& -\frac{3 C_{\eta, \tau}(1-4 \tau)}{4 \gamma} z^{T} K z+4 \gamma^{-3} L_{G}^{2}|z|^{2}+\frac{h \tau}{2} \gamma^{2}(1-2 \tau)|z|^{2} \\
& \leq-\frac{3 C_{\eta, \tau}}{8 \gamma} z^{T} K z+\frac{h \tau}{2} \gamma^{2}(1-2 \tau)|z|^{2} \leq-2 \tau \gamma \frac{(1-2 \tau)^{2}}{2}|z|^{2}
\end{aligned}
$$

Hence,

$$
\begin{aligned}
& (z, w)^{T}\left(h\left(M P_{1}+P_{1}^{T} M\right)+h^{2} P_{1}^{T} M P_{1}\right)(z, w) \\
& \leq C_{\eta, \tau} h(z, w)^{T}\left(\begin{array}{cc}
-2 \tau \gamma\left(\gamma^{-2} K+\frac{(1-2 \tau)^{2}}{2}\right) & -\tau(1-2 \tau) I_{d} \\
-\tau(1-2 \tau) I_{d} & -2 \tau \gamma^{-1} I_{d}
\end{array}\right)(z, w)+C_{\eta, \tau} h L_{G} \gamma^{-1} R^{2} \\
& \leq-2 C_{\eta, \tau} \tau \gamma h(z, w)^{T} M(z, w)+C_{\eta, \tau} h L_{G} \gamma^{-1} R^{2} \leq-\frac{7}{8} \tau \gamma h(z, w)^{T} M(z, w)
\end{aligned}
$$

where the last step holds by the definition of $\mathcal{R}$. We note that for $R=0, Q$ is positive definite and we can bound directly $-\frac{C_{\eta, \tau}(1-2 \tau)}{\gamma} Q+4 \gamma^{-3} Q^{2} \prec 0$, which yields the result.

Proof of Theorem 5. Fix $k \in \mathbb{N}$. Consider $\mathbf{X}_{k}, \mathbf{V}_{k}, \mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime} \in \mathbb{R}^{d}$. As for the Euler scheme, we write $Z_{k}=\mathbf{X}_{k}-\mathbf{X}_{k}^{\prime}, W_{k}=\mathbf{V}_{k}-\mathbf{V}_{k}^{\prime}$ and $q_{k}=Z_{k}+\gamma^{-1} W_{k}$. We show contraction separately for the synchronous coupling and the coupling given by (34).

Case 1: If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right) \leq r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right.$, the synchronous coupling is applied and it holds $\rho\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)=f\left(D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right)\right)$.

We observe

$$
\rho_{k+1}:=\rho\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right) \leq f\left(D_{\mathcal{K}}+\epsilon r_{l}(k+1)\right)
$$

where $r_{l}(k+1)=r_{l}\left(\left(\mathbf{X}_{k+1}, \mathbf{V}_{k+1}\right),\left(\mathbf{X}_{k+1}^{\prime}, \mathbf{V}_{k+1}^{\prime}\right)\right)$ By Proposition 14 and (15) it holds

$$
r_{l}(k+1) \leq \sqrt{1-\tau \gamma h} r_{l}(k) \leq\left(1-\frac{7 \tau \gamma h}{16}\right) r_{l}(k)
$$

By concavity of $f$, we obtain

$$
\begin{align*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq \mathbb{E}\left[f\left(D_{\mathcal{K}}+\epsilon r_{l}(k+1)\right)-f\left(D_{\mathcal{K}}+\epsilon r_{l}(k)\right)\right] \\
& \leq f^{\prime}\left(R_{1}\right) \epsilon \mathbb{E}\left[r_{l}(k+1)-r_{l}(k)\right] \leq-f^{\prime}\left(R_{1}\right) c_{1} h r_{l}(k) \tag{63}
\end{align*}
$$

where $c_{1}=7 \epsilon \tau \gamma / 16$ with $\tau$ given in Proposition 14. By (22),

$$
-f^{\prime}\left(R_{1}\right) c_{1} h r_{l}(k) \leq-f^{\prime}\left(R_{1}\right) h \frac{c_{1} r_{l}(k)}{D_{\mathcal{K}}+\epsilon r_{l}(k)} \rho_{k} \leq-f^{\prime}\left(R_{1}\right) c_{1} h \mathcal{E} \rho_{k}
$$

Case 2: If $D_{\mathcal{K}}+\epsilon r_{l}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)>r_{s}\left(\left(\mathbf{X}_{k}, \mathbf{V}_{k}\right),\left(\mathbf{X}_{k}^{\prime}, \mathbf{V}_{k}^{\prime}\right)\right.\right.$, the coupling (34) is applied. By the definition of the BU-scheme and (34), it holds for the process $\left(Z_{k}, q_{k}\right)_{k \in \mathbb{N}}$

$$
\left\{\begin{align*}
Z_{k+1} & =Z_{k}+(1-\eta)\left(q_{k}-Z_{k}\right)-\frac{h(1-\eta)}{\gamma}\left(\nabla U\left(\mathbf{X}_{k}\right)-\nabla U\left(\mathbf{X}_{k}^{\prime}\right)\right)  \tag{64}\\
& +\sqrt{2 \gamma^{-1} h}\left(1-\frac{1-\eta}{\gamma h}\right) \Xi_{k+1} \\
q_{k+1} & =q_{k}-h \gamma^{-1}\left(\nabla U\left(\mathbf{X}_{k}\right)-\nabla U\left(\mathbf{X}_{k}^{\prime}\right)\right)+\sqrt{2 \gamma^{-1} h} \Xi_{k+1}
\end{align*}\right.
$$

with $\eta=e^{-\gamma h}$. To show contraction for this scenario, we split the proof in three steps:
Step 1: Let $\left|Z_{k}\right| \geq 4\left|q_{k}\right|$. For $\left|Z_{k+1}\right|$ and $\left|q_{k}\right|$ it holds

$$
\begin{aligned}
\left|Z_{k+1}\right| & \leq\left|Z_{k}\right| \eta+\left|\eta-\frac{1-\eta}{\gamma h}\right|\left|q_{k}\right|+\frac{h(1-\eta)}{\gamma} L\left|Z_{k}\right|+\sqrt{2 \gamma^{-1} h}\left(1-\frac{1-\eta}{\gamma h}\right)\left|\hat{q}_{k}+\Xi_{k+1}\right| \\
\left|q_{k+1}\right| & \leq h \gamma^{-1} L\left|Z_{k}\right|+\sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|
\end{aligned}
$$

We observe

$$
\begin{aligned}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq & f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[r_{s}(k+1)-r_{s}(k)\right] \\
\leq & f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[\alpha\left|Z_{k}\right|\left(\eta+\frac{h \gamma}{2}+\frac{h \gamma \alpha(1-\eta)}{2}\right)+\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|\left|q_{k}\right|\right. \\
& \left.\quad+\sqrt{2 \gamma^{-1} h}\left(1+\left|1-\frac{1-\eta}{\gamma h}\right| \alpha\right)\left|\hat{q}_{k}+\Xi_{k+1}\right|-\left|q_{k}\right|-\alpha\left|Z_{k}\right|\right]
\end{aligned}
$$

By (37), it holds $\mathbb{E}\left[\left|\hat{q}_{k}+\Xi_{k+1}\right|\right]=\hat{q}_{k}$. Hence,

$$
\begin{aligned}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq f^{\prime}\left(r_{s}(k)\right)\left[\alpha\left|Z_{k}\right|\left[\left(\eta+\frac{h \gamma}{2}+\frac{h \gamma \alpha(1-\eta)}{2}\right)-1\right]\right. \\
& \left.+\alpha\left(\left|\eta-\frac{1-\eta}{\gamma h}\right|+\left|1-\frac{1-\eta}{\gamma h}\right|\right)\left|q_{k}\right|\right] \\
& \leq f^{\prime}\left(r_{s}(k)\right)\left[\alpha\left|Z_{k}\right|\left[\left(\eta+\frac{h \gamma}{2}+\frac{h \gamma \alpha(1-\eta)}{2}\right)-1\right]+\alpha(1-\eta)\left|Z_{k}\right| / 4\right]
\end{aligned}
$$

where we used in the second step $\eta=e^{-\gamma h} \leq \frac{1-\eta}{\gamma h} \leq 1$ and $\left|q_{k}\right| \leq\left|Z_{k}\right| / 4$. Using that by (15), $\frac{h \gamma}{2}+\frac{h \gamma \alpha}{2} \leq \frac{1}{12}+\frac{1}{24}=\frac{1}{8}$, we obtain

$$
\begin{aligned}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq f^{\prime}\left(r_{s}(k)\right) \alpha\left|Z_{k}\right|\left[\frac{h \gamma}{2} \eta+\left(\frac{3}{4}-\frac{h \gamma}{2}-\frac{h \gamma \alpha}{2}\right)(\eta-1)\right] \\
& \leq f^{\prime}\left(r_{s}(k)\right) \alpha\left|Z_{k}\right|\left(\frac{h \gamma}{2} \eta+\frac{5}{8} \eta(-\gamma h)\right) \leq f^{\prime}\left(r_{s}(k)\right) \alpha\left|Z_{k}\right|\left(-\frac{h \gamma}{8}\right) \eta \\
& \leq-f^{\prime}\left(R_{1}\right) \eta \min \left(\frac{h \gamma}{16}, \frac{h \gamma \alpha}{4}\right) \rho_{k}
\end{aligned}
$$

Step 2: Let $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right| \geq \sqrt{2 \gamma^{-1} h}$. First, using (15) we observe that similarly to the first case

$$
\alpha\left|Z_{k}\right|\left[(\eta-1)+\frac{h \gamma}{2}+\frac{\alpha \gamma h}{2}(1-\eta)-1\right] \leq 0
$$

and hence, we can bound

$$
\begin{equation*}
r_{s}(k+1) \leq \alpha\left|Z_{k}\right|+\alpha\left|\frac{1-\eta}{\gamma h}-\eta\right|\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left(1+\left|1-\frac{1-\eta}{\gamma h}\right| \alpha\right)\left|\hat{q}_{k}+\Xi_{k+1}\right|=: \bar{r}_{s}(k) \tag{65}
\end{equation*}
$$

Then, by concavity of $f$

$$
\begin{align*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] & \leq \mathbb{E}\left[f\left(\bar{r}_{s}(k)\right)-f\left(r_{s}(k)\right)\right] \\
& \leq f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[\bar{r}_{s}(k)-r_{s}(k)\right]+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \tag{66}
\end{align*}
$$

For the first term, it holds by (37) and $\eta \leq \frac{1-\eta}{\gamma h} \leq 1$,

$$
f^{\prime}\left(r_{s}(k)\right) \mathbb{E}\left[\bar{r}_{s}(k)-r_{s}(k)\right] \leq f^{\prime}\left(r_{s}(k)\right) \alpha(1-\eta)\left|q_{k}\right|
$$

To bound the second term we define

$$
\begin{equation*}
\bar{A}=\left\{\Xi_{k+1}=-\hat{q}_{k}\right\} \quad \text { and } \quad \bar{A}^{c}=\left\{\Xi_{k+1} \neq-\hat{q}_{k}\right\}=\left\{\Xi_{k+1}=2\left(e_{k} \cdot \xi_{k+1}^{(1)}\right) e_{k}\right\} \tag{67}
\end{equation*}
$$

and split the term in

$$
\begin{aligned}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \\
& \quad=\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right]+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right]
\end{aligned}
$$

Since $f^{\prime \prime}$ is non-positive, the first term satisfies

$$
\begin{align*}
& \mathbb{E} {\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] \leq \mathbb{E}\left[\int_{r_{s}(k)}^{\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] } \\
& \leq \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}}\right] \\
& \leq \frac{3\left(\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|-1\right)^{2}\left|q_{k}\right|^{2}}{8}  \tag{68}\\
& t \in\left[r_{s}(k)+\left(\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|-1\right) / 2\left|q_{k}\right|, r_{s}(k)\right] \\
& \max ^{\prime \prime}(t) \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right]
\end{align*}
$$

For the second term we define the set

$$
A^{\prime}=\left\{\sqrt{2 \gamma h^{-1}}\left|\hat{q}_{k}+\Xi_{k+1}\right| \leq\left|q_{k}\right|-\sqrt{2 \gamma^{-1} h}\right\} .
$$

Then,

$$
\begin{align*}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right]  \tag{69}\\
& \quad \leq \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), r_{s}(k)\right]} f^{\prime \prime}(t) \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] . \tag{70}
\end{align*}
$$

Next, we use the observation (45) for $f^{\prime \prime}(t)$ for $t \in\left[\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right), r_{s}(k)\right]$. By inserting the estimate in (68) and (70) and using $\left|q_{k}\right| \geq \sqrt{2 \gamma^{-1} h},\left|\eta-\frac{1-\eta}{\gamma h}\right| \leq 1-\eta \leq \gamma h$ and $\alpha \gamma h \leq 1 / 2$, we obtain

$$
\begin{equation*}
\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}}\right] \leq \frac{3 \gamma^{-1} h}{16}\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right] \tag{71}
\end{equation*}
$$

and

$$
\begin{aligned}
& \mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{\bar{A}^{c}}\right] \\
& \quad \leq\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] .
\end{aligned}
$$

The expectation on the right-hand side is bounded by

$$
\begin{aligned}
\mathbb{E} & {\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right] } \\
& =\int_{-\infty}^{\infty} \frac{3\left(\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|\left|q_{k}\right|+\sqrt{2 \gamma^{-1} h}\left(1+\left|1-\frac{1-\eta}{\gamma h}\right| \alpha\right)\left|\hat{q}_{k}+2 u\right|-\left|q_{k}\right|\right)^{2}}{8} \mathbb{1}_{\left\{\left|\hat{q}_{k}+2 u\right| \leq\left|\hat{q}_{k}\right|-1\right\}} \\
& \left.\left.=\int_{-\frac{\left|\hat{q}_{k}\right|}{2}}^{-\frac{1}{2}} \frac{\left.3(\alpha \mid u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u}{\gamma h} \frac{1-\eta}{h}| | q_{k} \right\rvert\,+\sqrt{2 \gamma^{-1} h}\left(1+\left|1-\frac{1-\eta}{\gamma h}\right| \alpha\right) 2 u\right)^{2} \\
8 & \geq \frac{3 \gamma^{-1} h}{4} \int_{-\frac{\left|\hat{q}_{k}\right|}{-\frac{1}{2}}}^{-\frac{1}{2}}\left(\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right| \frac{R_{1}}{\sqrt{2 \gamma^{-1} h}}+2 u\right)^{2}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{\left.\left.-\left|\hat{q}_{k}\right|\right)\right)^{+}}^{-\frac{1}{2}} \mathrm{~d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{-\frac{\left|\hat{q}_{k}\right|}{2}}^{-\frac{1}{2}}\left(\alpha(1-\eta) \frac{R_{1}}{\sqrt{2 \gamma_{k}-1} h}+2 u\right)^{2}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u \\
& \geq \frac{3 \gamma^{-1} h}{4} \int_{-\frac{\left|\hat{q}_{k}\right|}{2}}^{-\frac{1}{2}} \frac{1}{4}\left(\varphi(u)-\varphi\left(u+\left|\hat{q}_{k}\right|\right)\right)^{+} \mathrm{d} u,
\end{aligned}
$$

where in the second last step we used $\frac{\alpha(1-\eta) R_{1}}{\sqrt{2 \gamma^{-1} h}} \leq \frac{\alpha \gamma h R_{1}}{\sqrt{2 \gamma^{-1} h}} \leq 1 / 2$. Combining this bound and the expectation in (71) yields

$$
\mathbb{E}\left[\frac{3\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \mathbb{1}_{\bar{A}^{c}} \mathbb{1}_{A^{\prime}}\right]+\frac{3 \gamma^{-1} h}{16} \mathbb{E}\left[\mathbb{1}_{\bar{A}}\right] \geq \frac{3}{16} \gamma^{-1} h \int_{-\infty}^{-1 / 2} \varphi(u) \mathrm{d} u \geq \frac{9}{160} \gamma^{-1} h .
$$

Inserting this bound back into the sum of (68) and (70) and inserting the sum back into (66), we obtain

$$
\begin{aligned}
& \mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \\
& \quad \leq f^{\prime}\left(r_{s}(k)\right) \alpha(1-\eta)\left|q_{k}\right|+\frac{9}{160} \gamma^{-1} h\left(-128 \alpha \gamma^{2} \frac{r_{s}(k)}{4} f^{\prime}\left(r_{s}(k)\right)-\frac{\hat{c} \gamma}{4} f\left(r_{s}(k)\right)\right) \\
& \quad \leq-\frac{9}{640} \hat{c} h f\left(r_{s}(k)\right)=-\frac{9}{640} \hat{c} h \rho_{k} .
\end{aligned}
$$

Step 3: Let $\left|Z_{k}\right|<4\left|q_{k}\right|$ and $\left|q_{k}\right|<\sqrt{2 \gamma^{-1} h}$. As in the second step it holds

$$
\begin{equation*}
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq f^{\prime}\left(r_{s}(k)\right) \alpha \gamma h\left|q_{k}\right|+\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \tag{72}
\end{equation*}
$$

where $\bar{r}_{s}(k)$ is given by (65). The last term is bounded by

$$
\begin{aligned}
\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] & \leq \mathbb{E}\left[\int_{\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t \mathbb{1}_{A}\right] \\
& \leq \mathbb{E}\left[\frac{\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2}}{8} \max _{t \in\left[r_{s}(k), \frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right)\right]} f^{\prime \prime}(t) \mathbb{1}_{A}\right]
\end{aligned}
$$

where the set $A$ is given by

$$
\begin{equation*}
A=\left\{\left|q_{k}\right|+2 \sqrt{2 \gamma^{-1} h} \leq \sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right| \leq\left|q_{k}\right|+6 \sqrt{2 \gamma^{-1} h}\right\} \tag{73}
\end{equation*}
$$

By construction of $A$, it holds

$$
\frac{1}{2}\left(r_{s}(k)+\bar{r}_{s}(k)\right) \geq \frac{1}{2}\left|q_{k}\right|+\frac{1}{2} \sqrt{2 \gamma^{-1} h}\left(1+\left|1-\frac{1-\eta}{\gamma h}\right| \alpha\right)\left|\hat{q}_{k}+\Xi_{k+1}\right| \geq \sqrt{2 \gamma^{-1} h}
$$

By (15), it holds $8(7 \alpha \gamma h+6) \leq 50$ and $(7 \alpha \gamma h+6)(7 \alpha \gamma h+8) \leq 50$ and therefore by $(73)$

$$
\begin{aligned}
& \bar{r}_{s}(k)^{2}-r_{s}(k)^{2} \\
&= 2\left(\alpha\left|Z_{k}\right|+\left|q_{k}\right|\right)\left[\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|\left|q_{k}\right|+\left(1+\alpha\left|1-\frac{1-\eta}{\gamma h}\right|\right) \sqrt{2 \gamma^{-1} h} \hat{q}_{k}+\Xi_{k+1}\left|-\left|q_{k}\right|\right]\right. \\
&+\left(\alpha\left|\eta-\frac{1-\eta}{\gamma h}\right|\left|q_{k}\right|+\left(1+\alpha\left|1-\frac{1-\eta}{\gamma h}\right|\right) \sqrt{2 \gamma^{-1} h}\left|\hat{q}_{k}+\Xi_{k+1}\right|-\left|q_{k}\right|\right)^{2} \\
& \leq 2(4 \alpha+1)\left|q_{k}\right|\left(\alpha(1-\eta)\left|q_{k}\right|+6 \alpha(1-\eta) \sqrt{2 \gamma^{-1} h}+6 \sqrt{2 \gamma^{-1} h}\right) \\
&+\left(\alpha(1-\eta)\left|q_{k}\right|+6 \alpha(1-\eta) \sqrt{2 \gamma^{-1} h}+6 \sqrt{2 \gamma^{-1} h}\right)^{2} \\
& \leq\left(2 \gamma^{-1} h\right)\left(2(4 \alpha+1)(7 \alpha \gamma h+6)+(7 \alpha \gamma h+6)^{2}\right) \\
& \leq\left(2 \gamma^{-1} h\right)(8 \alpha(7 \alpha \gamma h+6)+(7 \alpha \gamma h+6)(7 \alpha \gamma h+8)) \leq\left(2 \gamma^{-1} h\right)(50 \alpha+50) .
\end{aligned}
$$

By (15), we observe

$$
\begin{aligned}
\frac{\phi\left(\bar{r}_{s}(k)\right)}{\phi\left(r_{s}(k)\right)} & =\exp \left(-128 \alpha \gamma^{2} \frac{\bar{r}_{s}(k)^{2}-r_{s}(k)^{2}}{2}\right) \geq \exp \left(-128 \alpha \gamma^{2} \frac{\left(2 \gamma^{-1} h\right)(50 \alpha+50)}{2}\right) \\
& \geq \exp (-2 / 3) \geq 1 / 2
\end{aligned}
$$

and also (45) holds. Using these bounds and (44), yields for all $t \in\left[\frac{1}{2}\left(\bar{r}_{s}(k)+r_{s}(k)\right), \bar{r}_{s}(k)\right]$

$$
f^{\prime \prime}(t) \leq-\frac{1}{4} f^{\prime}\left(r_{s}(k)\right) 128 \alpha \gamma^{2} \sqrt{2 \gamma^{-1} h}-\frac{\hat{c} \gamma}{4} \frac{\sqrt{2 \gamma^{-1} h}}{(4 \alpha+1)\left|q_{k}\right|} f\left(r_{s}(k)\right)
$$

where we used that $r_{s}(k) \leq(4 \alpha+1)\left|q_{k}\right|$. Hence, since on the set $A,\left(\bar{r}_{s}(k)-r_{s}(k)\right)^{2} \geq 2 \gamma^{-1} h$, it holds

$$
\begin{aligned}
\mathbb{E} & {\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] } \\
& \leq \frac{\left(2 \gamma^{-1} h\right)^{3 / 2}}{8}\left(-f^{\prime}\left(r_{s}(k)\right) 32 \alpha \gamma^{2}-\frac{\hat{c} \gamma}{4} \frac{1}{(4 \alpha+1)} f\left(r_{s}(k)\right)\right) \mathbb{E}\left[\mathbb{1}_{A}\right] .
\end{aligned}
$$

The term $\mathbb{E}\left[\mathbb{1}_{A}\right]$ is bounded as in (46). Hence,

$$
\mathbb{E}\left[\int_{r_{s}(k)}^{\bar{r}_{s}(k)}\left(\bar{r}_{s}(k)-t\right) f^{\prime \prime}(t) \mathrm{d} t\right] \leq-\gamma^{-1} h \alpha \gamma^{2} f^{\prime}\left(r_{s}(k)\right)\left|q_{k}\right|-\frac{1}{128(4 \alpha+1)} h \hat{c} f\left(r_{s}(k)\right) .
$$

Inserting this bound back into (72), we obtain

$$
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq-\frac{1}{128(4 \alpha+1)} h \hat{c} f\left(r_{s}(k)\right) .
$$

Putting the three steps together and combining the result with the first case, we obtain

$$
\mathbb{E}\left[\rho_{k+1}-\rho_{k}\right] \leq(1-c h) \rho_{k}
$$

with $c$ given in (17).
